July, 1920.

PREFACE.

This volume of the *American Ephemeris and Nautical Almanac*, the eighth to be issued under the international agreement resulting from the *Congrès International des Éphémérides Astronomiques* held at Paris in October, 1911, was prepared under the immediate supervision of Captain W. S. EICHELBERGER, Corps of Professors of Mathematics, U. S. N., the Director. The character of the matter herein contained and its arrangement are the same as in the immediately preceding volume.

The naval appropriation bill approved August 22, 1912, contained the following:

The Secretary of the Navy is hereby authorized to arrange for the exchange of data with such foreign almanac offices as he may from time to time deem desirable, with a view to reducing the amount of duplication of work in preparing the different national nautical and astronomical almanacs and increasing the total data which may be of use to navigators and astronomers available for publication in the *American Ephemeris and Nautical Almanac*: *Provided*, That any such arrangement shall be terminable on one year's notice: *Provided further*, That the work of the Nautical Almanac Office during the continuance of any such arrangement shall be conducted so that in case of emergency the entire portion of the work intended for the use of navigators may be computed by the force employed by that office, and without any foreign cooperation whatsoever: *Provided further*, That any employee of the Nautical Almanac Office who may be authorized in any annual appropriation bill and whose services in whole or in part can be spared from the duty of preparing for publication the annual volumes of the *American Ephemeris and Nautical Almanac* may be employed by said office in the duty of improving the tables of the planets, moon, and stars, to be used in preparing for publication the annual volumes of the office: *Provided further*, That section four hundred and thirty-five, Revised Statutes, is hereby repealed.

The Greenwich ephemerides of the Sun, Moon, Mercury, Venus, Mars, Jupiter, Saturn, Uranus, and Neptune were furnished by the office of the *British Nautical Almanac*.

The conjunctions, phenomena, and configurations of Jupiter's satellites I-IV and the apparent places for Greenwich transit of 38 circumpolar stars were furnished by the office of the *Connaissance des Temps*.

The apparent places for Greenwich transit of 121 ten-day stars were furnished by the office of the *Almanaque Nautico*.

The apparent places for Greenwich transit of 137 ten-day stars were furnished by the office of the *Annuario Astronomico di Torino*.

In accordance with the recommendations of the *Congrès International des Éphémérides Astronomiques*, most of the material furnished from abroad is based upon tables prepared in the American Nautical Almanac Office. In the Introduction are mentioned the various tables upon which the different ephemerides are based.

The following computations were made by the American Nautical Almanac Office:

In Part I, all the hourly and daily variations for the quantities furnished from abroad except in the case of the right ascension and declination of the Moon.

In Part II, the quantities used in computing the apparent places of the stars from their mean places; the mean place list; the interpolation of the apparent places of 214 stars from transit at Greenwich to transit at Washington; the apparent places of 611 stars; the interpolation of the ephemerides of the Sun, Moon, and planets from Greenwich noon to transit at Washington; the stellar magnitudes of the planets.

In Part III, the data relating to the eclipses of the Sun and Moon; the data relating to the occultations of stars and planets by the Moon; the ephemerides for physical observations of the Sun, Moon, Mars, and Jupiter; the elements of the illuminated disks of Mercury and Venus; the stellar magnitudes of the planets; the data concerning the satellites of the planets except Jupiter's satellites I-IV; the diagrams of the satellite orbits; the list of phenomena; the list of observatories with their geographical coordinates; the tables for the determination of latitude and azimuth from observations of Polaris; and the tables for the determination of the time of the rising and setting of the Sun and Moon.

All computations made in the American Nautical Almanac Office and those received from the other offices were subjected to checks to insure absence of errors.

J. A. HOOGEWERFF,
Rear Admiral, U. S. Navy,
Superintendent Naval Observatory.

WASHINGTON, *July, 1920.*

INTRODUCTION.

The ephemeris of the Sun is constructed from NEWCOMB'S *Tables of the Sun, Astronomical Papers of the American Ephemeris*, Vol. VI, part 1.

The adopted value of the mean equatorial horizontal parallax of the Sun is 8''.80, *Paris Conference, May, 1896*.

The Sun's rectangular equatorial coordinates are computed from the longitudes and latitudes by the following formulæ:

$$\begin{aligned} X &= R \cos \lambda \\ Y &= R \sin \lambda \cos \omega - 19.3 R \beta \\ Z &= R \sin \lambda \sin \omega + 44.5 R \beta \end{aligned}$$

The reductions to mean equinox are computed by the formulæ—

$$\begin{aligned} \Delta X &= + Y \sec \omega \Delta \lambda \sin 1'' \\ \Delta Y &= -X \cos \omega \Delta \lambda \sin 1'' + Z \Delta \omega \sin 1'' + 9.1 \tau R \sin (\lambda + 6^\circ) \\ \Delta Z &= -X \sin \omega \Delta \lambda \sin 1'' - Y \Delta \omega \sin 1'' - 21.0 \tau R \sin (\lambda + 6^\circ) \end{aligned}$$

where the numerical coefficients are in units of the seventh place of decimals and

R = the Sun's distance from the Earth,

λ = the Sun's true longitude,

β = the Sun's true latitude, expressed in seconds of arc,

ω = the obliquity of the ecliptic,

$\Delta \lambda$ = the reduction of longitude for precession and nutation from the beginning of the Besselian fictitious year,

$\Delta \omega$ = the reduction of the mean to the apparent obliquity,

τ = the fraction of the year since the beginning of the Besselian fictitious year.

The longitude, latitude, and parallax of the Moon are derived from BROWN'S new *Tables of the Motion of the Moon* (in manuscript).

The ephemerides of Mercury, Venus, and Mars are derived from NEWCOMB'S tables of these planets, *Astronomical Papers of the American Ephemeris*, Vol. VI, parts 2, 3, and 4. Corrections derived from *Astronomical Papers of the American Ephemeris*, Vol. IX, part 2, have been applied to the ephemeris of Mars.

The ephemerides of Jupiter and Saturn are derived from the tables constructed in this office by GEORGE W. HILL, *Astronomical Papers of the American Ephemeris*, Vol. VII, parts 1 and 2.

The ephemerides of Uranus and Neptune are derived from NEWCOMB'S tables of these planets, *Astronomical Papers of the American Ephemeris*, Vol. VII, parts 3 and 4.

The nutation used in computing the ephemerides of the Sun, Moon, and planets has been taken from Tables XXXII and XXXIII of NEWCOMB'S *Tables of the Sun, Astronomical Papers of the American Ephemeris*, Vol. VI, part 1. The formulæ from which this nutation is computed are as follows, the time interval T being expressed in units of 100 years, reckoned from 1900. See *Tables of the Sun*, page 26.

$$\begin{array}{ll}
 \delta\psi = -(17''.234 + 0''.017 T) \sin \Omega & \delta\epsilon = +9''.214 \cos \Omega \\
 + 0''.209 \sin 2 \Omega & -0''.090 \cos 2 \Omega \\
 - 1''.257 \sin 2 L & +0''.546 \cos 2 L \\
 - 0''.049 \sin (3 L + 78^\circ.7) & +0''.021 \cos (3 L + 78^\circ.7) \\
 + 0''.110 \sin (L + 75^\circ.3) & -0''.009 \cos (L - 78^\circ.7)
 \end{array}$$

The formulæ for the nutation used in computing the Besselian and Independent Star Numbers are as follows:

Terms of Long Period.	Terms of Short Period.
$\delta\psi = -(17''.234 + 0''.017 T) \sin \Omega$	$-0''.204 \sin 2 \zeta$
$+ 0''.209 \sin 2 \Omega$	$+0''.011 \sin (\zeta + \Gamma')$
$- 1''.272 \sin 2 L$	$+0''.068 \sin (\zeta - \Gamma')$
$+ 0''.126 \sin (L - \Gamma)$	$-0''.034 \sin (2 \zeta - \Omega)$
$- 0''.050 \sin (3 L - \Gamma')$	$-0''.026 \sin (3 \zeta - \Gamma')$
$+ 0''.021 \sin (L + \Gamma)$	$+0''.015 \sin (\zeta - 2 L + \Gamma')$
$+ 0''.012 \sin (2 L - \Omega)$	$+0''.006 \sin 2 (\zeta - L)$
$\delta\epsilon = + (9''.210 + 0''.0009 T) \cos \Omega$	$+0''.088 \cos 2 \zeta$
$- 0''.090 \cos 2 \Omega$	$+0''.018 \cos (2 \zeta - \Omega)$
$+ 0''.551 \cos 2 L$	$+0''.011 \cos (3 \zeta - \Gamma')$
$+ 0''.022 \cos (3 L - \Gamma)$	$-0''.005 \cos (\zeta + \Gamma')$
$- 0''.009 \cos (L + \Gamma)$	
$- 0''.007 \cos (2 L - \Omega)$	

The meaning of the symbols used and the manner in which these latter formulæ have been employed in computing the ephemerides of the stars are explained on pages 200 and 201. The slight discrepancy between the terms in 2 L in these two sets of formulæ is due to the correction of an error in the first set. See *Bulletin Astronomique*, 1898, Vol. XV, page 244.

The list of 825 stars contained in Part II has been selected from NEWCOMB'S *Catalogue of Fundamental Stars, Astronomical Papers of the American Ephemeris*, Vol. VIII, part 2.

In general, the names of the stars are the same as in NEWCOMB'S Suggested List of Fundamental Stars, except that the FLAMSTEED number has been omitted in all cases where Greek or italic letters are available. In some cases the constellation and number of the uranometries of HEIS or GOULD have been used. In all such cases, H¹ or the letter G precedes the constellation name, as, for example, 5 H¹. Cassiopeiæ and 38 G. Horologii.

The magnitudes of the stars have, with a few exceptions, been taken from *Annals of the Harvard College Observatory*, Vol. L, 1908.

The spectral classification has been furnished by the Harvard College Observatory. The notation is that of *Annals of Harvard College Observatory*, Vol. LVI.

The mean places, annual variations, and annual proper motions of the stars have been taken from NEWCOMB'S Catalogue, except that those of

ϵ Hydri, 38 G. Horologii, and π Centauri have been taken from *Veroeffentlichungen des Koeniglichen Astronomischen Rechen-Institut zu Berlin*, 1907, No. 33.

The values of $\Delta\alpha$ and $\Delta\delta$, which are given for the companions to the stars γ Andromedæ, α^1 Crucis, ζ^1 Ursæ Majoris, and 61 Cygni, have been taken from BOSS's *Preliminary General Catalogue*, and those for α^2 Geminorum from DOBERCK's elements given in the *Astronomische Nachrichten*, 1904, vol. 166, page 145.

The formulæ for the computation of the Besselian and Independent Star Numbers are given on page 200, the coefficients being those given by NEWCOMB in *Bulletin Astronomique*, 1898, Vol. XV, page 241.

The terms of short period of the nutation, depending on the Moon's mean longitude, have been computed from the formulæ for these terms given above.

The method by which the right ascensions and declinations of the stars interpolated from the 10-day ephemerides are corrected for the effect of these short-period terms is given on page 201.

According to the formulæ on pages 200 and 201 the star constants a , b , c , d , a' , b' , c' , d' are computed for each star from its mean place at the beginning of the year, but if strict accuracy is required they should be computed from the star's mean place at date, and the following second-order terms should be added to the usual expressions for the reduction from mean to apparent place, namely—

To $\alpha - \alpha_0$	To $\delta - \delta_0$
$ \begin{aligned} &+0.000\ 003\ \tau^2 \sin \alpha \Big\} \tan \delta \\ &-0.000\ 149\ \tau^2 \cos \alpha \Big\} \tan \delta \\ &-0.000\ 0650\ \tau^2 \sin 2\alpha \\ &+0.000\ 0103\ \sin 2\ \odot \cos 2\alpha \Big\} \tan^2 \delta \\ &-0.000\ 0107\ \cos 2\ \odot \sin 2\alpha \Big\} \tan^2 \delta \\ &+0.000\ 0620\ \sin 2\ \odot \cos 2\alpha \Big\} \sec^2 \delta \\ &-0.000\ 0622\ \cos 2\ \odot \sin 2\alpha \Big\} \sec^2 \delta \\ &+0.000\ 0513\ \sin (\odot + \odot) \cos 2\alpha \Big\} \tan \delta \sec \delta \\ &-0.000\ 0507\ \cos (\odot + \odot) \sin 2\alpha \Big\} \tan \delta \sec \delta \\ &+0.000\ 0097\ \sin (\odot - \odot) \cos 2\alpha \Big\} \tan \delta \sec \delta \\ &-0.000\ 0053\ \cos (\odot - \odot) \sin 2\alpha \Big\} \tan \delta \sec \delta \end{aligned} $	$ \begin{aligned} &+0.000\ 975\ \tau^2 \sin^2 \alpha \\ &-0.000\ 023\ \cos 2\ \odot \\ &-0.000\ 080\ \cos 2\ \odot \cos 2\alpha \Big\} \tan \delta \\ &-0.000\ 077\ \sin 2\ \odot \sin 2\alpha \Big\} \tan \delta \\ &+0.000\ 040\ \cos 2\ \odot \\ &-0.000\ 467\ \cos 2\ \odot \cos 2\alpha \Big\} \sin \delta \tan \delta \\ &-0.000\ 465\ \sin 2\ \odot \sin 2\alpha \Big\} \sin \delta \tan \delta \\ &-0.000\ 039\ \cos (\odot + \odot) \\ &-0.000\ 380\ \cos (\odot + \odot) \cos 2\alpha \Big\} \sin \delta \tan \delta \\ &-0.000\ 385\ \sin (\odot + \odot) \sin 2\alpha \Big\} \sin \delta \tan \delta \\ &-0.000\ 380\ \cos (\odot - \odot) \\ &-0.000\ 040\ \cos (\odot - \odot) \cos 2\alpha \Big\} \sin \delta \tan \delta \\ &-0.000\ 072\ \sin (\odot - \odot) \sin 2\alpha \Big\} \sin \delta \tan \delta \end{aligned} $

These terms are negligible for stars whose declination is numerically less than 80° , but in computing the apparent places given in the American Ephemeris they have been applied whenever sensible.

The *apparent* places of seven stars have been corrected for the effect of annual parallax. These stars, with the adopted values of the annual parallax, are—

τ Ceti	0.31	α Centauri	0.75
ϵ Eridani	0.32	α Aquilæ (Altair)	0.23
α Canis Majoris (Sirius) .	0.38	61 Cygni	0.30
α Canis Minoris (Procyon)	0.33		

The *apparent* places of α Canis Majoris (Sirius), α Canis Minoris (Procyon), and α^2 Centauri have been corrected for the effect of orbital motion. AUWERS's

elements were used for Sirius and Procyon, and SEE's elements for α^2 Centauri. The values of these corrections are given on pages 98 and 99 of *Veroeffentlichungen des Koeniglichen Astronomischen Rechen Instituts zu Berlin*, 1907, No. 33, but those for Sirius and Procyon need an additional correction to refer them to the center of the orbit before they are applicable to the mean places taken from NEWCOMB's Fundamental Catalogue. These additional corrections for Sirius and Procyon were omitted in the *Star List of the American Ephemeris* [Supplement to the *American Ephemeris and Nautical Almanac*] for 1910 and 1911, and in the *American Ephemeris and Nautical Almanac* for 1912 and 1913. The values of the corrections for the three stars are—

	Sirius.		Procyon.		α^2 Centauri.	
	1923.0	1924.0	1923.0	1924.0	1923.0	1924.0
$\Delta\alpha$	-0 ^s .131	-0 ^s .126	-0 ^s .021	-0 ^s .009	+0 ^s .554	+0 ^s .535
$\Delta\delta$	-1 ^{''} .29	-1 ^{''} .38	+0 ^{''} .70	+0 ^{''} .74	+4 ^{''} .15	+3 ^{''} .82

These corrections have not been applied to the mean places as published in this volume.

The stars occulted by the Moon have been selected from the *Catalogue of Zodiacal Stars* contained in Vol. VIII, part 3, *Astronomical Papers of the American Ephemeris*, and the mean places have been derived from the same catalogue.

In Part III the elements of eclipses of the Sun and occultations of stars by the Moon are given in accordance with BESSEL's method, the special forms employed being a modification of those developed in CHAUVENET's *Spherical and Practical Astronomy*.

In the computation of the elements of eclipses, the following corrections to the longitude and latitude of the Moon have been applied. These corrections, corresponding to a correction of +7^{''}.0 in mean longitude and -0^{''}.5 in latitude, have been assumed in each case to be constant during the eclipse.

G. M. T.	$\delta\lambda$	$\delta\delta$
1923	"	"
Mar. 2 ^d . 16 ^h	+7.9	+0.2
Mar. 17 1	+6.3	-1.1
Aug. 25 23	+6.8	-1.1
Sept. 10 9	+7.8	+0.2

The elongations of the satellites of Mars are derived from elements given by H. STRUVE in *Sitzungsberichte der Königlich Preussischen Akademie der Wissenschaften*, 1911, page 1073.

The conjunctions and phenomena of Jupiter's four brighter satellites are derived from SAMPSON's tables. The configurations are derived from a continuation of DAMOISEAU's tables by M. POTTIER.

The elongations of the Vth satellite of Jupiter are derived from unpublished elements deduced from the observations of BARNARD.

The differential coordinates of Jupiter's VIth and VIIth satellites are derived from elements and tables given in *Lick Observatory Bulletin*, 1906, Vol. IV, No. 112, and in *Astronomische Nachrichten*, 1907, Vol. 174, page 359, respectively.

The positions of the rings and the elongations and conjunctions of the satellites of Saturn are derived from elements given by H. STRUVE in *Observations de Poulkova*, Supplement 1, St. Petersburg, 1888; *Publications de Poulkovo*, Second Series, Vol. XI, St. Petersburg, 1898; with corrections communicated by H. STRUVE to the *Berliner Jahrbuch*. The differential coordinates of Phœbe are derived from elements and tables given in *Annals of Harvard College Observatory*, 1905, Vol. LIII, No. VI.

The apparent outer dimensions (a and b) of the rings of Saturn are also according to STRUVE; the relative dimensions of the rings are computed from BESSEL's data, except those for the dusky ring, which are based on the observations of various astronomers.

The elongations of Ariel and Umbriel, the inner satellites of Uranus, are derived from the data of NEWCOMB's *Uranian and Neptunian Systems*, *Washington Observations*, 1873, Appendix I. The elongations of Titania and Oberon, the outer satellites of Uranus, are derived from elements given by H. STRUVE in *Abhandlungen der K. Preussischen Akademie der Wissenschaften*, 1912.

The elongations of the satellite of Neptune are derived from elements given by A. HALL in the *Astronomical Journal*, 1898, Vol. XIX, page 65.

The adopted apparent semidiameter of the Sun at the Earth's mean distance is $16' 1''.50$, while in the computation of eclipses the value given by AUWERS in the *Astronomische Nachrichten*, 1891, Vol. 128, page 367, is employed, viz., $15' 59''.63$.

In the computation of the ephemeris for physical observations of the Sun the following elements by CARRINGTON have been used:

Inclination of the Sun's equator to the ecliptic	$7^{\circ} 15'$
Longitude of the ascending node of the Sun's equator on the ecliptic	$73^{\circ} 40' + 50''.25 (t-1850)$
Sidereal period of rotation (mean solar days)	$25^d 4.38$

The apparent semidiameter of the Moon is computed from the Moon's equatorial horizontal parallax, π , by the formula,

$$S = 0.272\,469\,\pi + 1''.50$$

where the constant 0.272 469 is derived from the equatorial horizontal parallax given on page xvi and the semidiameter given on page xvii; and the constant $1''.50$ is added to cover the average effect of irradiation.

The value of the Moon's semidiameter employed in the computation of eclipses is computed from the formula,

$$\sin S = 0.272\,274 \sin \pi$$

In the computation of the ephemeris for physical observations of the Moon, the following notation and formulæ have been used, the value of I and the formulæ for physical libration being those given by F. HAYN in *Abhandlungen der K. Sächsischen Gesell. der Wissenschaften*, Vols. 29 and 30, 1904, 1907:

I —the inclination of the Moon's mean equator to the ecliptic ($=1^{\circ} 32'.1$),

Ω —the longitude of the ascending node of the Moon's orbit, or the longitude of the descending node of the Moon's mean equator,

C —the angle at the center of the Moon's disk made by a lunar meridian with the circle of declination, counted from north to east,

- $\lambda, \beta, \alpha, \delta$ = the geocentric longitude, latitude, right ascension, and declination of the Moon,
 i = the inclination of the Moon's mean equator to the Earth's true equator,
 Δ = the distance on the Moon's mean equator from its ascending node on the Earth's true equator to its ascending node on the ecliptic,
 Ω' = the distance along the Earth's true equator from the true equinox to the ascending node of the Moon's mean equator,
 ζ = the Moon's mean longitude, referred to the mean equinox,
 g' = the Earth's mean anomaly,
 g = the Moon's mean anomaly,
 ω = the angular distance of the perigee of the Moon's orbit from its ascending node on the ecliptic,
 b, l = the optical librations in latitude and longitude, respectively,
 $\delta b, \delta l$ = the physical librations in latitude and longitude, respectively,
 $b + \delta b$ = the Moon's geocentric libration in latitude = the Earth's selenographic latitude,
 $l + \delta l$ = the Moon's geocentric libration in longitude = the Earth's selenographic longitude,
 δC = the physical libration of C ,
 $\mu = -0'.617 \sin 2 (\Omega - \lambda)$,
 $A = \sin I \cos (\Omega - \lambda)$,
 $\tan B = \tan I \sin (\Omega - \lambda)$,
 $\lambda' = \lambda + \mu + Ab$,
 $b = B - \beta$,
 $l = \lambda' - \zeta$,
 $\sin C' = \sin i \frac{\cos (\lambda' + \Delta - \Omega)}{\cos \delta} = -\sin i \frac{\cos (\alpha - \Omega')}{\cos b}$,
 $\delta b = +108'' \sin (\omega + l) + 37'' \sin (\omega - l) - 11'' \sin (g + \omega - l)$,
 $\delta l = +12'' \sin g - 59'' \sin g' - 18'' \sin 2\omega$,
 $-[108'' \cos (\omega + l) - 37'' \cos (\omega - l) + 11'' \cos (g + \omega - l)] \tan b$,
 $\delta C = -[108'' \cos (\omega + l) - 37'' \cos (\omega - l) + 11'' \cos (g + \omega - l)] \sec b$,
 $C = C' + \delta C$.

The Sun's selenographic latitude and longitude have been computed from formulae the same as those given above except that the heliocentric coordinates of the Moon have been substituted for the geocentric coordinates.

The following elements have been used in computing the ephemerides for physical observations of the planets Mars and Jupiter:

Position of north pole of Mars	$\left\{ \begin{array}{l} \alpha = 21^{\text{h}} 10^{\text{m}} 0^{\text{s}} + 1^{\text{s}}.565(t-1905) \\ \delta = 54^{\circ} 30' 0'' + 12''.60(t-1905) \end{array} \right.$
Position of north pole of Jupiter	$\left\{ \begin{array}{l} \alpha = 17^{\text{h}} 52^{\text{m}} 0^{\text{s}}.84 + 0^{\text{s}}.247(t-1910) \\ \delta = 64^{\circ} 33'.34''.6 - 0''.60(t-1910) \end{array} \right.$
Rotation period of Mars	$24^{\text{h}} 37^{\text{m}} 22^{\text{s}}.65$
Rotation period of Jupiter { System I.	$9^{\text{h}} 50^{\text{m}} 30^{\text{s}}.004$
{ System II.	$9^{\text{h}} 55^{\text{m}} 40^{\text{s}}.632$
Longitude of Central Meridian of Mars, May 15, 1897, Greenwich	
Mean Noon	$52^{\circ}.01$
Longitude of Central Meridian of Jupiter (System I.), July 14, 1897, Greenwich Mean Noon	
	$47^{\circ}.31$
Longitude of Central Meridian of Jupiter (System II.), July 14, 1897, Greenwich Mean Noon	
	$96^{\circ}.58$

The position of the north pole of Mars is as given by LOWELL and CROMMELIN (see *Monthly Notices R. A. S.*, 1905, Vol. 66, page 56), while that of the north pole of Jupiter has been deduced from the position given by DAMOISEAU for 1750 (see *Tables Écliptiques des Satellites de Jupiter*, page (1)). The rotation periods of Mars and of Jupiter and the longitudes of the central meridians are according to MARTIN (see *Monthly Notices R. A. S.*, 1896, Vol. 56, pages 395-403 and 517-524).

The adopted semidiameters of the planets, with the authority for each, are given on page xvii. Their stellar magnitudes have been computed from formulæ given by G. MUELLER in *Publicationen des Astrophysikalischen Observatoriums zu Potsdam*, 1893, Vol. 8, page 366.

In the list of observatories the authority for the various positions is given in each case. The latitudes given are in most cases astronomical. In some instances they have been determined by geodetic triangulation from other points. The reductions from geographic to geocentric latitude, $\varphi' - \varphi$, and the distance from the center of the earth, ρ , are computed from the formulæ on page xvi, using the flattening $\frac{1}{297}$ obtained by JOHN F. HAYFORD in *Supplementary Investigation in 1909 of the Figure of the Earth and Isostasy*, U. S. Coast and Geodetic Survey, 1910, and adopted by the *Paris Conference*, October, 1911.

ANNIVERSARIES AND FESTIVALS, 1923.

New Year's Day	Monday, Jan. 1.
Epiphany	Saturday, Jan. 6.
Septuagesima Sunday	Sunday, Jan. 28.
Quinquagesima (Shrove Sunday)	Sunday, Feb. 11.
Lincoln's Birthday	Monday, Feb. 12.
Ash Wednesday	Wednesday, Feb. 14.
Washington's Birthday	Thursday, Feb. 22.
Palm Sunday	Sunday, Mar. 25.
Good Friday	Friday, Mar. 30.
First Day of Passover	Sunday, Apr. 1.
Easter Sunday	Sunday, Apr. 1.
Rogation Sunday	Sunday, May 6.
Ascension Day	Thursday, May 10.
Pentecost (Whit Sunday)	Sunday, May 20.
Hebrew Pentecost (Shebuoth)	Monday, May 21.
Trinity Sunday	Sunday, May 27.
Memorial Day	Wednesday, May 30.
Corpus Christi	Thursday, May 31.
Independence Day	Wednesday, July 4.
Labor Day	Monday, Sept. 3.
Hebrew New Year (Rosh Hashanah)	Tuesday, Sept. 11.
Day of Atonement (Yom Kippur)	Thursday, Sept. 20.
First Day of Feast of Tabernacles (Succoth)	Tuesday, Sept. 25.
Columbus Day	Friday, Oct. 12.
Election Day (in certain States)	Tuesday, Nov. 6.
Thanksgiving Day	Thursday, Nov. 29.
First Sunday in Advent	Sunday, Dec. 2.
Christmas Day	Tuesday, Dec. 25.

CHRONOLOGICAL ERAS AND CYCLES.

CHRONOLOGICAL ERAS.

The year 1923 of the Christian era comprises the latter part of the 147th and the beginning of the 148th year of the independence of the United States of America, and corresponds to the year 6636 of the Julian period.

Of the peoples using the Christian era some employ the Gregorian calendar and some the Julian. January 1, 1923, Julian calendar, corresponds to January 14, 1923, Gregorian calendar.

The year 7432 of the Byzantine era begins on September 1, 1923, Julian calendar.

The year 5684 of the Jewish era begins at sunset on September 10, 1923, Gregorian calendar.

The year 2676 since the foundation of Rome, according to VARRO, begins on January 1, 1923, Julian calendar.

The year 2672 of the era of NABONASSAR begins on April 30, 1923, Julian calendar.

The year 2583 of the Japanese era, being the 12th year of the period Taisho, begins on January 1, 1923, Gregorian calendar.

The year 2235 of the Grecian era, or the era of the SELEUCIDÆ, begins in the present-day usage of the Syrians on September 1, 1923, or on October 1, 1923, Julian calendar, according to different sects; but in the ancient usage of Damascus and Arabia Petraea the year began with the vernal equinox.

The year 1640 of the era of DIOCLETIAN begins on August 30, 1923, Julian calendar.

The year 1342 of the Mohammedan era, or the era of the Hegira, begins at sunset on August 13, 1923, Gregorian calendar.

2 423 421 is the Julian day number of January 1, 1923, Gregorian calendar.

CHRONOLOGICAL CYCLES.

Anomalistic	$\frac{d}{27.554\ 550-27\ 13\ 18\ 33.1}$	$\frac{h}{27}$	$\frac{m}{13}$	$\frac{s}{18\ 33.1}$	
Nodical	$\frac{d}{27.212\ 220-27\ 5\ 5\ 35.8}$	$\frac{h}{27}$	$\frac{m}{5}$	$\frac{s}{5\ 35.8}$	

Length of the day:			
Sidereal	$\frac{h}{23\ 56}$	$\frac{m}{4.091}$	$\frac{s}{\text{of mean solar time.}}$
Mean Solar	$\frac{h}{24\ 3}$	$\frac{m}{56.555}$	$\frac{s}{\text{of sidereal time.}}$

Dimensions of the Earth (Hayford's Spheroid of 1909):

Equatorial Radius, $a=6378.388$ kilometers or 3963.34 statute miles.

Polar Radius, $b=6356.909$ " or 3949.99 " "

Flattening, $\frac{a-b}{a}=\frac{1}{297.0}$

Logarithm of the eccentricity $\frac{\sqrt{a^2-b^2}}{a}=\log e=8.913\ 804$

Logarithm radius= $\log \rho=9.999\ 2695+0.000\ 7324 \cos 2\varphi-0.000\ 0019 \cos 4\varphi$.

Reduction from geographic latitude φ to geocentric latitude φ' ,

$$\varphi'-\varphi=-11' 35''.66 \sin 2\varphi+1''.17 \sin 4\varphi.$$

1 degree of latitude (in statute miles)=69.0569-0.3494 $\cos 2\varphi+0.0007 \cos 4\varphi$.

1 degree of longitude (in statute miles)=69.2316 $\cos \varphi-0.0584 \cos 3\varphi+0.0001 \cos 5\varphi$.

1 meter=3.280 8333 feet. 1 foot=0.304 8006 meters.

1 statute mile=0.868 362 nautical or geographical miles.

1 nautical mile=1.151 594 statute miles.

* *k*² is the acceleration due to the Sun's attraction at the mean distance of the Earth from the Sun, which is also the astronomical unit of distance, the unit of time being one mean solar day.

† φ =latitude, h =elevation above sea level in meters, and $\log R=6.80416$.

NOTE.—The above values of $\log \rho$ and $\varphi'-\varphi$ were computed with the eccentricity that results from assuming that the flattening of the earth is exactly $1+297$.

The elements of the four inner planets are derived from those given by NEWCOMB in Vol. VI of the *Astronomical Papers of the American Ephemeris*, with the corrections for Mars given in Vol. IX, Part II, of the *Astronomical Papers* added, and are the same as those used in computing the ephemerides of these planets. Those of Jupiter, Saturn, Uranus, and Neptune are taken from Vol. VII of the *Astronomical Papers* for the epoch of the tables. They are reduced to 1923 by applying LE VERRIER'S variations, and can not be regarded as being strictly identical with the elements used in computing the ephemerides of those planets in this volume.

* At mean distance. See *Ast. Papers Am. Eph.*, Vol. IX, p. 39. For the values of the semidiameter used in this volume see page xi.

† By mean least distance is meant the difference between the mean distance and unity.

‡ Mass includes satellite system, if any. Mass of Earth without Moon has the logarithm 4.476 9900-10.

PART II.

ASTRONOMICAL EPHEMERIS FOR THE MERIDIAN OF WASHINGTON.

200 FORMULÆ FOR THE REDUCTION OF STARS, 1923.

The constants of precession, nutation, and aberration adopted by the *Conférence Internationale des Étoiles Fondamentales* which met in Paris in May, 1896, are given on page xvi, and together with the notation of BESSEL are used in the formulæ which follow.

BESSELIAN STAR-NUMBERS.

<i>Terms of Long Period.</i>	<i>Terms of Short Period.</i>
$A-\tau = 0.342\ 22 \sin \Omega$	$-0.004\ 05 \sin 2 \mathfrak{C}$
$+ 0.004\ 15 \sin 2 \Omega$	$+0.000\ 23 \sin (\mathfrak{C} + \Gamma')$
$- 0.025\ 26 \sin 2 L$	$+0.001\ 31 \sin (\mathfrak{C} - \Gamma')$
$+ 0.002\ 51 \sin (L - \Gamma)$	$-0.000\ 68 \sin (2 \mathfrak{C} - \Omega)$
$- 0.000\ 99 \sin (3 L - \Gamma)$	$-0.000\ 52 \sin (3 \mathfrak{C} - \Gamma')$
$+ 0.000\ 42 \sin (L + \Gamma)$	$+0.000\ 30 \sin (\mathfrak{C} - 2 L + \Gamma')$
$+ 0.000\ 25 \sin (2 L - \Omega)$	$+0.000\ 12 \sin 2 (\mathfrak{C} - L)$
"	"
$B = -9.210 \cos \Omega$	$-0.088 \cos 2 \mathfrak{C}$
$+ 0.090 \cos 2 \Omega$	$-0.018 \cos (2 \mathfrak{C} - \Omega)$
$- 0.551 \cos 2 L$	$-0.011 \cos (3 \mathfrak{C} - \Gamma')$
$- 0.022 \cos (3 L - \Gamma)$	$+0.005 \cos (\mathfrak{C} + \Gamma')$
$+ 0.009 \cos (L + \Gamma)$	
$+ 0.007 \cos (2 L - \Omega)$	
$C = -20''.4700 \cos \omega \cos \odot$	
$D = -20''.4700 \sin \odot$	
$E = -0''.0412 \sin \Omega + 0''.0005 \sin 2 \Omega - 0''.0030 \sin 2 L$	

BESSEL'S Star-Constants.

$a = 3^s.072\ 76 + 1^s.336\ 33 \sin \alpha_0 \tan \delta_0$	$a' = 20''.0449 \cos \alpha_0$
$b = \frac{1}{15} \cos \alpha_0 \tan \delta_0$	$b' = -\sin \alpha_0$
$c = \frac{1}{15} \cos \alpha_0 \sec \delta_0$	$c' = \tan \omega \cos \delta_0 - \sin \alpha_0 \sin \delta_0$
$d = \frac{1}{15} \sin \alpha_0 \sec \delta_0$	$d' = \cos \alpha_0 \sin \delta_0$

Formulæ for Reduction to Apparent Position.

$$\alpha = \alpha_0 + \tau\mu + Aa + Bb + Cc + Dd + \frac{1}{15}E \quad (\text{in time})$$

$$\delta = \delta_0 + \tau\mu' + Aa' + Bb' + Cc' + Dd' \quad (\text{in arc})$$

INDEPENDENT STAR-NUMBERS.

$$f + f' = +46''.0914 A + E \quad (\text{in arc})$$

$$= +3^s.07276 A + \frac{1}{15}E \quad (\text{in time})$$

$$f' = -0^s.0124 \sin 2 \mathfrak{C} + 0^s.0041 \sin (\mathfrak{C} - \Gamma') + 0^s.0007 \sin (\mathfrak{C} + \Gamma')$$

$$- 0^s.0021 \sin (2 \mathfrak{C} - \Omega) - 0^s.0016 \sin (3 \mathfrak{C} - \Gamma')$$

$$+ 0^s.0009 \sin (\mathfrak{C} - 2 L + \Gamma') + 0^s.0004 \sin 2 (\mathfrak{C} - L)$$

$$g \sin G = B \qquad h \sin H = C \qquad i = C \tan \omega$$

$$g \cos G = 20''.0449 A \qquad h \cos H = D$$

Formulæ for Reduction to Apparent Position.

$$\alpha = \alpha_0 + f + f' + \tau\mu + \frac{1}{15}g \sin (G + \alpha_0) \tan \delta_0 + \frac{1}{15}h \sin (H + \alpha_0) \sec \delta_0 \quad (\text{in time})$$

$$\delta = \delta_0 + \tau\mu' + g \cos (G + \alpha_0) + h \cos (H + \alpha_0) \sin \delta_0 + i \cos \delta_0 \quad (\text{in arc})$$

In the above formulæ,

τ denotes the time reckoned in units of one year, from the beginning of the Besselian fictitious year (1923, January 0^d.670, Washington mean time),

α_0, δ_0 , the star's mean R. A. and Decl. at the beginning of the fictitious year,
 α, δ , the star's apparent right ascension and declination at the time τ ,
 μ, μ' , the annual proper motion in right ascension and declination,

\odot , the Sun's true longitude,
 L , the Sun's mean longitude,
 Ω , the longitude of the Moon's ascending node,

ω , the obliquity of the ecliptic,
 Γ , the long. of the Sun's perigee,
 Γ' , the long. of the Moon's perigee,
 \mathfrak{C} , the Moon's mean longitude.

FORMULÆ FOR THE REDUCTION OF STARS, 1923. 201

The independent star-numbers are more convenient than BESSEL's when only one or two apparent positions of a star are required, or when BESSEL's star-constants are not known with sufficient accuracy.

In using the star-constants of the *British Association Catalogue*, $a, b, c, d, a', b', c', d'$, with the star-numbers of this Ephemeris, the quantities to be computed are $Ac, Bd, Ca, Db, -Ac', -Bd', -Ca', -Db'$.

In the computation of the Besselian star-numbers given for Washington mean midnight of each day of the year, on pages 202-205, the short-period terms—that is, the terms involving the Moon's mean longitude—have been included.

In the computation of the independent star-numbers, pages 206-213, the short-period terms have been included in the two columns headed G and $\text{Log } g$. The quantities f and f' give separately the effect of the long-period and short-period terms. f' differs but slightly from the quantity $-0''.1866 \sin 2 \text{ } \mathfrak{C} + 0''.0622 \sin (\text{ } \mathfrak{C} - \Gamma')$ given on page 37 of the *Procès-Verbaux* of the Paris Conference of 1896, which quantity that conference decided should be omitted in the reduction of stars from mean to apparent place.

In computing the ephemerides of the circumpolar stars in this volume, all short-period terms have been included. The quantity f' , which was omitted from the ephemerides of the circumpolar stars given in the *American Ephemeris and Nautical Almanac* for the years 1900 to 1915, inclusive, is now included in these ephemerides in accordance with the decision of the *Congrès International des Éphémérides Astronomiques* held in Paris in October, 1911. See page 43 of *Procès-Verbaux* of that Congress.

In the computation of the ephemerides of the ten-day stars, no short-period terms have been included. These terms attain two maxima and two minima during the tropical month. At maximum and minimum they may amount in right ascension to $\pm(0''.020 + 0''.008 \tan \delta)$, and in declination to $\pm 0''.13$. For computing the effect of these terms for the correction of the positions of stars interpolated from the ten-day ephemerides, the following formulæ may be used, in which $\Delta\alpha$ and $\Delta\delta$ denote the effect of the short-period terms in right ascension and declination, respectively, and $\delta''\psi$ and $\delta''\omega$, the sum of the short-period terms of the nutation in longitude and obliquity:

$$\begin{aligned}\Delta\alpha &= D\psi\alpha \delta''\psi + D\omega\alpha \delta''\omega \\ \Delta\delta &= D\psi\delta \delta''\psi + D\omega\delta \delta''\omega\end{aligned}$$

The values of $\delta''\psi$ and of $\delta''\omega$ for Washington mean midnight are given for each day of the year on pages 215-216, and have been computed as follows:

$$\delta''\psi = 50''.37 A_2 \qquad \delta''\omega = -B_2$$

in which A_2 and B_2 are the sums of the short-period terms given in the expressions for A and B on page 200.

The quantities $D\psi\alpha, D\omega\alpha, D\psi\delta$, and $D\omega\delta$ are given for each ten-day star on pages 316-513, and have been computed by means of the following formulæ:

$$\begin{aligned}D\psi\alpha &= \frac{1}{15} (\cos \omega + \sin \alpha \tan \delta \sin \omega) & D\omega\alpha &= -\frac{1}{15} \cos \alpha \tan \delta \\ D\psi\delta &= \cos \alpha \sin \omega & D\omega\delta &= \sin \alpha\end{aligned}$$

In the *Star List of the American Ephemeris* for the years 1910 and 1911 and in the *American Ephemeris and Nautical Almanac* for the years 1912 to 1915, inclusive, the value used for the derivative of the right ascension with reference to ψ was

$$D'\psi\alpha = \frac{1}{15} \sin \alpha \tan \delta \sin \omega$$

and the addition of the term $\frac{1}{15} \cos \omega$ is made in accordance with the above-mentioned decision of the *Congrès International des Éphémérides Astronomiques* of 1911 with reference to the quantity f' .

E = -0.001

The above numbers give the same reductions from mean to apparent place as are employed in computing the apparent places of the stars, given on pages 316 to 513, from the mean places, given on pages 217 to 230. In order to render exact interpolation possible through intervals of ten days, all short-period terms have been omitted.

Stellar magnitude at opposition in February, 1923, 7.7.

PART III.

PHENOMENA.

In the year 1923 there will be four eclipses, two of the Sun and two of the Moon.

I.—*A Partial Eclipse of the Moon*, March 2, 1923, visible at Washington; the beginning visible generally in western Asia, Europe, Africa, the Atlantic Ocean, South America, North America except in the extreme northwestern part, and the eastern part of the Pacific Ocean; the ending visible generally in Europe, Africa except the eastern part, the Atlantic Ocean, North America, South America, and the eastern part of the Pacific Ocean.

ELEMENTS OF THE ECLIPSE.

Greenwich mean time of φ in right ascension, March 2				d	h	m	s
				2	15	57	27.0
Sun's right ascension	h	m	s	22	51	57.76	
Moon's right ascension	h	m	s	10	51	57.76	
Sun's declination	°	'	"	-7	13	50.1	
Moon's declination	°	'	"	+6	21	59.4	
Sun's equa. hor. parallax						8.9	
Moon's equa. hor. parallax				60	43.2		
Hourly motion							9.34
Hourly motion							143.76
Hourly motion							+ 0 57.2
Hourly motion							-11 0.7
Sun's true semidiameter						16	8.0
Moon's true semidiameter						16	31.9

CIRCUMSTANCES OF THE ECLIPSE.

Moon enters penumbra	March	d	h	m	} Greenwich Mean Time.
Moon enters umbra		2	13	12.6	
Middle of the eclipse		2	14	27.8	
Moon leaves umbra		2	15	31.8	
Moon leaves penumbra		2	16	35.8	
		2	17	50.8	
Contacts of Umbra with Moon's Limb.	Angles of Position from the North Point.	The Moon being in the Zenith in Longitude from Greenwich, and in Latitude.			
First	54 to E.	+	34	42	+6 38
Last	20 to W.	+	65	31	+6 15

Magnitude of the eclipse=0.376 (Moon's diameter=1.0).

II.—*An Annular Eclipse of the Sun*, March 16–17, 1923, invisible at Washington.

ELEMENTS OF THE ECLIPSE.

Greenwich mean time of δ in right ascension, March 17				d	h	m	s
				17	0	24	3.6
Sun and Moon's R. A.	h	m	s	23	44	56.02	
Sun's declination	°	'	"	-1	37	55.0	
Moon's declination	°	'	"	-2	8	47.1	
Sun's equa. hor. parallax						8.8	
Moon's equa. hor. parallax				54	13.6		
Hourly motions							9.14 and 113.74
Hourly motion							+0 59.3
Hourly motion							+9 17.8
Sun's true semidiameter						16	4.2
Moon's true semidiameter						14	45.8

CIRCUMSTANCES OF THE ECLIPSE.

	March	Greenwich Mean Time.			Longitude from Greenwich.	Latitude.
		d	h	m		
Eclipse begins		16	21	50.4	+56 43	-38 5
Central eclipse begins		16	23	5.5	+76 13	-50 49
Central eclipse at local apparent noon		17	0	24.1	+ 3 50	-36 40
Central eclipse ends		17	2	23.8	-56 40	-15 25
Eclipse ends		17	3	38.9	-37 31	- 2 39

III.—*A Partial Eclipse of the Moon*, August 25–26, 1923, visible at Washington; the beginning visible generally in North America except the extreme northeastern part, the western part of South America, the Pacific Ocean, Australia except the extreme southwestern part, and the extreme northeastern part of Asia; the ending visible generally in North America except the northeastern part, the extreme northwestern part of South America, the Pacific Ocean, Australia, and the eastern part of Asia.

ELEMENTS OF THE ECLIPSE.

Greenwich mean time of δ in right ascension, Aug. 25						
					d	h m s
Sun's right ascension	h	m	s			
	10	16	40.28	Hourly motion		9.17
Moon's right ascension	22	16	40.28	Hourly motion		124.32
Sun's declination	+10	42	5.9	Hourly motion	–	5 51.8
Moon's declination	–	9	49 6.1	Hourly motion	+	8 39.0
Sun's equa. hor. parallax			8.7	Sun's true semidiameter		15 49.7
Moon's equa. hor. parallax	55	57.7		Moon's true semidiameter		15 14.2

CIRCUMSTANCES OF THE ECLIPSE.

In the above table, P is the position-angle of the axis of rotation measured eastward from the north point of the disk, while B_0 and L_0 are the heliographic latitudes and longitudes, respectively, of the center of the disk. The longitudes are reckoned from the Solar Meridian which passed through the ascending node of the Sun's equator on the ecliptic, on January 1, 1854, Greenwich Mean Noon.

NOTATION.

k—the ratio of the area of the illuminated portion of the apparent disk to the area of the entire apparent disk regarded as circular.

i—the angle between the Sun and Earth, as seen from the planet.

θ —the angle which the line joining the cusps, or extremities of the illuminated portion, makes with the meridian.

L—the brilliancy of the disk. The unit of *L* is the amount of light received by an eye from a circular disk with the same albedo as the planet, subtending an angular radius of one second of arc, situated at distance unity from the Sun, and illuminated by the latter as the mean disk of the planet is illuminated.

FOR GREENWICH MEAN NOON.

By reason of the proximity of JUPITER to the SUN the phenomena of the satellites are not given from October 30 to December 16.

NOTE.—I. denotes ingress; E., egress; D., disappearance; R., reappearance; Ec., eclipse; Oc., occultation; Tr., transit of the satellite; Sh., transit of the shadow.

*Visible at Washington.

The factor to be multiplied by *a* and *b* to obtain the axes of—

The inner ellipse of the outer ring=0.8801, log factor=9.9445

The outer ellipse of the inner ring=0.8599, log factor=9.9344

The inner ellipse of the inner ring=0.6650, log factor=9.8228

The inner ellipse of the dusky ring=0.5486, log factor=9.7392

NOTE.—The positive sign of *B* indicates that the visible surface of the rings is the northern one.

GREENWICH MEAN TIME.

In the diagram on the preceding page the points of the orbits marked "0" are those of the eastern elongation, as seen in an inverting telescope. The times of these elongations may be found from the following tables, and the apparent position of a satellite at any other time may be marked on the diagram by setting off on the proper orbit the elapsed interval in days and hours since the last eastern elongation. The orbits of the five inner satellites are regarded as circular, and the time of any greatest elongation not given in the tables may be readily found from those given by adding or subtracting the proper multiple of the mean synodic period. For Titan, Hyperion, and Iapetus the eccentricity is taken into account, and for Iapetus the time both of the greatest elongations and of the conjunctions are given. The following abbreviations are used in the tables:

- E., Eastern Elongation.
W., Western Elongation.
- I., Inferior Conjunction (south of planet).
S., Superior Conjunction (north of planet).

MIMAS.

Greatest Elongations Visible in the United States.

Uranus is in opposition September 8, 1923, but at this date the Earth is very near the plane of the orbits of the satellites, and hence the apparent orbits approximate straight lines. For this reason the diagram of the apparent orbits is not given.

For Ariel every third greatest elongation is given, and for Umbriel every alternate one; the intermediate ones may be found by adding multiples of the period of the satellite.
Sidereal period of Ariel, 2^d 12^h.489; of Umbriel, 4^d 3^h.460; of Titania, 8^d 16^h.941; of Oberon, 13^d 11^h.118.

h And the new value of the longitude of Sydney.

THE COMPUTATION OF LUNAR DISTANCES.

Tables of lunar distances are no longer given in the Ephemeris, in accordance with the decision of the Navy Department that they are now of little practical use to navigators. However, in case it is desired to use this method, the angular distance between the Moon and any heavenly body may be calculated by solving the spherical triangle of which the known parts are the polar distances of the Moon and the other body and the difference of their right ascensions, or, in other words, the angle at the pole between their hour-circles. Then, the Greenwich mean time of the observation being approximately known, and the lunar distances for the star or other body calculated for the even hour before and after, the required lunar distance may be interpolated and the longitude derived by the methods given in books on navigation.

EXAMPLE 1.

Find the lunar distance of Aldebaran, February 28, 1923, at 10 P. M., Greenwich Mean Time.

Let α and δ = Right Ascension and Declination of the star

" α' and δ' = " " " " " " Moon

" D = Lunar Distance

Also let $\tan M = \tan \delta' \sec (\alpha - \alpha')$

Then $\cos D = \sin \delta' \cos (M - \delta) \operatorname{cosec} M$

α	4 ^h 31 ^m 30 ^s .5	M	29° 35' 23''
α'	8 ^h 42 ^m 15 ^s .0	δ	+16° 21' 11''
$\alpha - \alpha'$	19 ^h 49 ^m 15 ^s .5	$M - \delta$	13° 14' 12''
$\alpha - \alpha'$	297° 18' 52''	$\sin \delta'$	9.401658
δ'	+ 14° 36' 17''	$\cos (M - \delta)$	9.988306
$\tan \delta'$	9.415922	$\operatorname{cosec} M$	0.306461
$\sec (\alpha - \alpha')$	0.338307	$\cos D$	9.696425
$\tan M$	9.754229	D	60° 11' 35''

EXAMPLE 2.

Find the lunar distance of Jupiter, March 8, 1923, at noon, Greenwich Mean Time. In this case the distance is smaller and the following method is more accurate:

Let α and δ = Right Ascension and Declination of the planet

" α' and δ' = " " " " " " Moon

" D = Lunar Distance

Also let $\tan N = \tan \frac{1}{2} (\alpha - \alpha') \cos \frac{1}{2} (\delta + \delta') \operatorname{cosec} \frac{1}{2} (\delta - \delta')$

Then $\sin \frac{1}{2} D = \sin \frac{1}{2} (\alpha - \alpha') \cos \frac{1}{2} (\delta + \delta') \operatorname{cosec} N$

$\sin N$ and $\sin \frac{1}{2} (\alpha - \alpha')$ have the same algebraic sign.

α	15 ^h 7 ^m 19 ^s .1	$\tan \frac{1}{2} (\alpha - \alpha')$	9.043745 n
α'	15 ^h 57 ^m 48 ^s .5	$\cos \frac{1}{2} (\delta + \delta')$	9.983230
$\alpha - \alpha'$	23 ^h 9 ^m 30 ^s .6	$\operatorname{cosec} \frac{1}{2} (\delta - \delta')$	2.130022 n
$\alpha - \alpha'$	347° 22' 39''	$\tan N$	1.156997
δ	- 16° 14' 42''	N	86° 0' 54''
δ'	- 15° 23' 44''	$\sin \frac{1}{2} (\alpha - \alpha')$	9.041105
$\delta + \delta'$	- 31° 38' 26''	$\cos \frac{1}{2} (\delta + \delta')$	9.983230
$\delta - \delta'$	- 0° 50' 58''	$\operatorname{cosec} N$	0.001051
$\frac{1}{2} (\alpha - \alpha')$	173° 41' 20''	$\sin \frac{1}{2} D$	9.025386
$\frac{1}{2} (\delta + \delta')$	- 15° 49' 13''	$\frac{1}{2} D$	6° 5' 9''
$\frac{1}{2} (\delta - \delta')$	- 0° 25' 29''	D	12° 10' 18''

FOR FINDING THE LATITUDE BY AN OBSERVED ALTITUDE OF POLARIS, 1923.

Reduce the observed altitude of Polaris to the true altitude.

Reduce the recorded time of observation to the local sidereal time.

Take out the apparent right ascension and declination of Polaris for the time of observation.

Subtract the apparent right ascension from the local sidereal time of observation and the remainder is the hour-angle of Polaris.

With this hour-angle as the vertical argument, and the apparent declination of Polaris as the horizontal argument, take out the correction from Table I and add it to or subtract it from the true altitude, according to its sign.

For altitudes other than 45° , corrections taken from the supplementary table at the bottom of Table I (Table Ia) may be applied when necessary for the degree of accuracy required.

Example.—August 5, 1923, at $10^h 40^m 30^s$ P. M. local mean solar time, in longitude 59° west of Greenwich, suppose the true altitude of Polaris to be $33^\circ 20' 0''$, required the latitude of the place.

Local astronomical mean time	h	m	s
Reduction from Table III for $10^h 40^m 30^s$	10	40	30
Greenwich sidereal time of mean noon, August 5, page 10	8	52	3
Reduction from Table III for longitude ($=3^h 56^m$ west, or plus)	+ 0	39	
Sum (having regard to signs) is equal to local sidereal time	19	34	57
R. A. of Polaris (page 281) for time of observation	1	34	15
Remainder is equal to hour-angle of Polaris	18	0	42
Decl. of Polaris (page 281) for time of observation, $88^\circ 53' 21''$.	.	.
True altitude	+33	20	0
Correction from Table I	+ 0	27	
Correction from Table Ia			-13
Latitude of the place	+33	20	14

Observations of Polaris for latitude should be made when practicable near the times of upper or of lower culminations (hour-angle 0^h or 12^h). However, at sea, if made near elongation (hour-angle 6^h or 18^h), the hour-angle, and hence the local time, should be known within one minute.

Decl.	88° 53' 20''	88° 53' 30''	88° 53' 40''	88° 53' 50''	88° 54' 0''	88° 54' 10''	Decl.

TABLE Ia.

Table I has been computed for an altitude of 45°. For other altitudes, corrections taken from the following table may be applied when the desired degree of accuracy requires it.

Altitude. H. A.		10°	20°	30°	40°	50°	60°	70°	Altitude. H. A.	
h	h	"	"	"	"	"	"	"	h	h

TABLE IVa.

Table IV has been computed for a declination of 88° 53' 40''. For other declinations of Polaris the corrections given below should be applied to the Azimuth taken from Table IV.

Decl.	Azimuth.											Azimuth.	Decl.
	0'	20'	40'	60'	80'	100'	120'	140'	160'	180'	200'

* Sidereal time from elongation.

FOR FINDING THE TIMES OF UPPER AND LOWER CULMINATION OF POLARIS, 1923, FROM THE OBSERVED TIMES WHEN THE STAR IS ON THE SAME VERTICAL CIRCLE WITH THE STARS ζ URSÆ MAJORIS (MIZAR) *SUB POLO* AND δ CASSIOPEIÆ *SUB POLO*, RESPECTIVELY.

Except at high latitudes, the pole star at either upper or lower culmination furnishes a simple and convenient method for laying down a meridian line on the earth's surface at points in the northern hemisphere. When the local time is unknown and accurate astronomical instruments are not available, the time of culmination of Polaris may be found by observing the instant when Polaris is vertically above (has the same azimuth as) ζ Ursa Majoris (Mizar) below the pole, or δ Cassiopeia below the pole. In the former case, for the year 1923, Polaris is approaching upper culmination and in the latter case it is approaching lower culmination. The mean time interval which elapses between either of the observed times above mentioned and upper or lower culmination, as the case may be, is given at ten-day intervals in the following table. This method can not be used at places south of 30° north latitude.

ζ URSÆ MAJORIS (MIZAR). (Upper culmination of Polaris.)							δ CASSIOPEIÆ. (Lower culmination of Polaris.)

APPARENT PLACE, TIME OF UPPER CULMINATION, AND TIME INTERVAL BETWEEN UPPER CULMINATION AND ELONGATION EAST OR WEST, OF POLARIS, 1923.

The local mean time of culmination on any meridian for a given date is found by taking from the following table the *Mean Time* of the nearest Greenwich culmination, and applying to it the product of the *Var. per Day* by the integral number of intervening days, this product being numerically additive for an earlier date and subtractive for a later date than that given in the table; and by applying also the product of the *Var. per Hour* by the longitude from Greenwich expressed in hours and fractions of an hour, this product being numerically additive for East longitudes and subtractive for West longitudes.

The time interval between upper and lower culmination is 12^h diminished by one-half the numerical value of the *Var. per Day*.

The last column below applies to all meridians.

Date.	Upper Culmination, Meridian of Greenwich.					Latitude.	Mean Time Interval, Elongation minus Upper Culm.
	Apparent Right Ascension.	Apparent Declination.	Mean Time.	Var. per Day.	Var. per Hour.

LOCAL ASTRONOMICAL MEAN TIME OF SUNRISE (SUN'S UPPER LIMB),
MERIDIAN OF GREENWICH, 1923.

To obtain civil time, subtract 12 hours, mark the result A. M., and add one to the day.

To obtain the standard time at any station, increase the local time by the number of minutes the station is west of the standard meridian, or decrease the local time by the number of minutes the station is east of the standard meridian.

For sunrise in southern latitudes see page 726.

TABLE VIII.

711

LOCAL ASTRONOMICAL MEAN TIME OF SUNSET (SUN'S UPPER LIMB),
MERIDIAN OF GREENWICH, 1923.

To obtain civil time, write P. M. after the astronomical time.

To obtain the standard time at any station, increase the local time by the number of minutes the station is west of the standard meridian, or decrease the local time by the number of minutes the station is east of the standard meridian.

For sunset in southern latitudes see page 726.

LOCAL ASTRONOMICAL MEAN TIME OF SUNRISE (SUN'S UPPER LIMB),
MERIDIAN OF GREENWICH, 1923.

To obtain civil time, subtract 12 hours, mark the result A. M., and add one to the day.

To obtain the standard time at any station, increase the local time by the number of minutes the station is west of the standard meridian, or decrease the local time by the number of minutes the station is east of the standard meridian.

For sunrise in southern latitudes see page 726.

TABLE VIII.

713

LOCAL, ASTRONOMICAL MEAN TIME OF SUNSET (SUN'S UPPER LIMB),
MERIDIAN OF GREENWICH, 1923.

To obtain civil time; write P. M. after the astronomical time.

To obtain the standard time at any station, increase the local time by the number of minutes the station is west of the standard meridian, or decrease the local time by the number of minutes the station is east of the standard meridian.

For sunset in southern latitudes see page 726.

LOCAL ASTRONOMICAL MEAN TIME OF SUNRISE (SUN'S UPPER LIMB),
MERIDIAN OF GREENWICH, 1923.

To obtain civil time, subtract 12 hours, mark the result A. M., and add one to the day.

To obtain the standard time at any station, increase the local time by the number of minutes the station is west of the standard meridian, or decrease the local time by the number of minutes the station is east of the standard meridian.

For sunrise in southern latitudes see page 726.

TABLE VIII.

715

LOCAL ASTRONOMICAL MEAN TIME OF SUNSET (SUN'S UPPER LIMB),
MERIDIAN OF GREENWICH, 1923.

To obtain civil time, write P. M. after the astronomical time.

To obtain the standard time at any station, increase the local time by the number of minutes the station is west of the standard meridian, or decrease the local time by the number of minutes the station is east of the standard meridian.

For sunset in southern latitudes see page 726.

LOCAL ASTRONOMICAL MEAN TIME OF SUNRISE (SUN'S UPPER LIMB),
MERIDIAN OF GREENWICH, 1923.

To obtain civil time, subtract 12 hours, mark the result A. M., and add one to the day.

To obtain the standard time at any station, increase the local time by the number of minutes the station is west of the standard meridian, or decrease the local time by the number of minutes the station is east of the standard meridian.

For sunrise in southern latitudes see page 726.

TABLE VIII.

717

LOCAL ASTRONOMICAL MEAN TIME OF SUNSET (SUN'S UPPER LIMB), MERIDIAN OF GREENWICH, 1923.

To obtain civil time, write P. M. after the astronomical time.

To obtain the standard time at any station, increase the local time by the number of minutes the station is west of the standard meridian, or decrease the local time by the number of minutes the station is east of the standard meridian.

For sunset in southern latitudes see page 726.

LOCAL ASTRONOMICAL MEAN TIME OF SUNRISE (SUN'S UPPER LIMB),
MERIDIAN OF GREENWICH, 1923.

To obtain civil time, subtract 12 hours, mark the result A. M., and add one to the day.

To obtain the standard time at any station, increase the local time by the number of minutes the station is west of the standard meridian, or decrease the local time by the number of minutes the station is east of the standard meridian.

For sunrise in southern latitudes see page 726.

TABLE VIII.

719

LOCAL ASTRONOMICAL MEAN TIME OF SUNSET (SUN'S UPPER LIMB),
MERIDIAN OF GREENWICH, 1923.

To obtain civil time, write P. M. after the astronomical time.

To obtain the standard time at any station, increase the local time by the number of minutes the station is west of the standard meridian, or decrease the local time by the number of minutes the station is east of the standard meridian.

For sunset in southern latitudes see page 726.

TABLE VIII.

LOCAL ASTRONOMICAL MEAN TIME OF SUNRISE (SUN'S UPPER LIMB),
MERIDIAN OF GREENWICH, 1923.

To obtain civil time, subtract 12 hours, mark the result A. M., and add one to the day.

To obtain the standard time at any station, increase the local time by the number of minutes the station is west of the standard meridian, or decrease the local time by the number of minutes the station is east of the standard meridian.

For sunrise in southern latitudes see page 726.

TABLE VIII.

721

LOCAL ASTRONOMICAL MEAN TIME OF SUNSET (SUN'S UPPER LIMB),
MERIDIAN OF GREENWICH, 1923.

To obtain civil time, write P. M. after the astronomical time.

To obtain the standard time at any station, increase the local time by the number of minutes the station is west of the standard meridian, or decrease the local time by the number of minutes the station is east of the standard meridian.

For sunset in southern latitudes see page 726.

LOCAL ASTRONOMICAL MEAN TIME OF SUNRISE (SUN'S UPPER LIMB),
MERIDIAN OF GREENWICH, 1923.

To obtain civil time, subtract 12 hours, mark the result A. M., and add one to the day.

To obtain the standard time at any station, increase the local time by the number of minutes the station is west of the standard meridian, or decrease the local time by the number of minutes the station is east of the standard meridian.

For sunrise in southern latitudes see page 726.

TABLE VIII.

723

LOCAL ASTRONOMICAL MEAN TIME OF SUNSET (SUN'S UPPER LIMB),
MERIDIAN OF GREENWICH, 1923.

To obtain civil time, write P. M. after the astronomical time.

To obtain the standard time at any station, increase the local time by the number of minutes the station is west of the standard meridian, or decrease the local time by the number of minutes the station is east of the standard meridian.

For sunset in southern latitudes see page 726.

Lat. Date.	0°	+10°	+20°	+30°	+35°	+40°	+45°	+50°	+52°	+54°	+56°	+58°	+60°

LOCAL ASTRONOMICAL MEAN TIME OF SUNRISE (SUN'S UPPER LIMB),
MERIDIAN OF GREENWICH, 1923.

To obtain civil time, subtract 12 hours, mark the result A. M., and add one to the day.

To obtain the standard time at any station, increase the local time by the number of minutes the station is west of the standard meridian, or decrease the local time by the number of minutes the station is east of the standard meridian.

For sunrise in southern latitudes see page 726.

TABLE VIII.

725

LOCAL ASTRONOMICAL MEAN TIME OF SUNSET (SUN'S UPPER LIMB), MERIDIAN OF GREENWICH, 1923.

To obtain civil time, write P. M. after the astronomical time.

To obtain the standard time at any station, increase the local time by the number of minutes the station is west of the standard meridian, or decrease the local time by the number of minutes the station is east of the standard meridian.

For sunset in southern latitudes see page 726.

TABLE IX.

SUNRISE AND SUNSET FOR SOUTHERN LATITUDES, 1923.

In the case of a southern latitude the time of sunrise or sunset is taken from Table VIII, with the corresponding northern latitude, not for the given date but for a date about six months earlier or later, which is to be found in the following table. The time taken from Table VIII, whether of sunrise or of sunset, must be corrected by the quantity given in Table IX on the same line with the given date.

Example.—May 10, 1923, civil date, in latitude -38° , required the time of sunrise and sunset.

The astronomical date is May 9 for sunrise and May 10 for sunset; Table IX gives November 11 and 12 as the corresponding dates, northern latitude, while the correction is $+12^m$ in each case.

LOCAL ASTRONOMICAL MEAN TIME OF MOONRISE (MOON'S UPPER LIMB),
MERIDIAN OF GREENWICH, 1923.

To obtain civil time, write P. M. after the astronomical time if it is less than twelve hours; if greater than twelve hours, subtract twelve hours from it, mark the result A. M., and add one to the day.

To obtain standard time, see directions on page 710.

For other longitudes and for southern latitudes see page 744.

LOCAL ASTRONOMICAL MEAN TIME OF MOONSET (MOON'S UPPER LIMB),
MERIDIAN OF GREENWICH, 1923.

To obtain civil time, write P. M. after the astronomical time if it is less than twelve hours; if greater than twelve hours, subtract twelve hours from it, mark the result A. M., and add one to the day.

To obtain standard time, see directions on page 710.

For other longitudes and for southern latitudes see page 744.

TABLE X.

731

LOCAL ASTRONOMICAL MEAN TIME OF MOONSET (MOON'S UPPER LIMB), MERIDIAN OF GREENWICH, 1923.

To obtain civil time, write P. M. after the astronomical time if it is less than twelve hours; if greater than twelve hours, subtract twelve hours from it, mark the result A. M., and add one to the day.

To obtain standard time, see directions on page 710.

For other longitudes and for southern latitudes see page 744.

LOCAL ASTRONOMICAL MEAN TIME OF MOONSET (MOON'S UPPER LIMB),
MERIDIAN OF GREENWICH, 1923.

To obtain civil time, write P. M. after the astronomical time if it is less than twelve hours; if greater than twelve hours, subtract twelve hours from it, mark the result A. M., and add one to the day.

To obtain standard time, see directions on page 710.

For other longitudes and for southern latitudes see page 744.

LOCAL ASTRONOMICAL MEAN TIME OF MOONSET (MOON'S UPPER LIMB),
MERIDIAN OF GREENWICH, 1923.

To obtain civil time, write P. M. after the astronomical time if it is less than twelve hours; if greater than twelve hours, subtract twelve hours from it, mark the result A. M., and add one to the day.

To obtain standard time, see directions on page 710.

For other longitudes and for southern latitudes see page 744.

737

LOCAL ASTRONOMICAL MEAN TIME OF MOONSET (MOON'S UPPER LIMB), MERIDIAN OF GREENWICH, 1923.

To obtain civil time, write P. M. after the astronomical time if it is less than twelve hours; if greater than twelve hours, subtract twelve hours from it, mark the result A. M., and add one to the day.

To obtain standard time, see directions on page 710.

For other longitudes and for southern latitudes see page 744.

LOCAL ASTRONOMICAL MEAN TIME OF MOONRISE (MOON'S UPPER LIMB),
MERIDIAN OF GREENWICH, 1923.

To obtain civil time, write P. M. after the astronomical time if it is less than twelve hours;
if greater than twelve hours, subtract twelve hours from it, mark the result A. M., and add one
to the day.

To obtain standard time, see directions on page 710.
For other longitudes and for southern latitudes see page 744.

LOCAL ASTRONOMICAL MEAN TIME OF MOONRISE (MOON'S UPPER LIMB),
MERIDIAN OF GREENWICH, 1923.

To obtain civil time, write P. M. after the astronomical time if it is less than twelve hours;
if greater than twelve hours, subtract twelve hours from it, mark the result A. M., and add one
to the day.

To obtain standard time, see directions on page 710.
For other longitudes and for southern latitudes see page 744.

LOCAL ASTRONOMICAL MEAN TIME OF MOONRISE (MOON'S UPPER LIMB),
MERIDIAN OF GREENWICH, 1923.

To obtain civil time, write P. M. after the astronomical time if it is less than twelve hours; if greater than twelve hours, subtract twelve hours from it, mark the result A. M., and add one to the day.

To obtain standard time, see directions on page 710.

For other longitudes and for southern latitudes see page 744.

FOR NORTHERN STATIONS NOT ON THE MERIDIAN OF GREENWICH, AND FOR SOUTHERN STATIONS.

For northern stations not on the meridian of Greenwich.—For longitudes twelve hours or less west from Greenwich obtain the data for the given latitude from Table X for the given date and for the date following; for longitude twelve hours or less east from Greenwich obtain the data for the given latitude from Table X for the given date and for the date preceding. Subtract the time on the earlier date from the time on the later and multiply the difference by the twenty-fourth part of the longitude in hours and decimals of an hour, positive if west, negative if east. Apply the product as a correction to the time on the given date.

For southern stations.—The instant of moonrise or moonset for any station south of the equator is that of moonset or moonrise, respectively, at a place of the same latitude north of the equator whose longitude is twelve hours different from that at the southern station.

If the southern station is twelve hours or less west from Greenwich, and the phenomenon at that station occurs between noon and midnight, the local astronomical day will be the same at the southern and northern stations. If, however, the phenomenon at the southern station occurs between midnight and noon, the local astronomical day at the northern station will be one day later than at the southern.

If the southern station is twelve hours or less east from Greenwich, and the phenomenon at that station occurs between noon and midnight, the local astronomical day at the northern station will be one less than at the southern station. If, however, the phenomenon occurs between midnight and noon, the local astronomical day will be the same at the two stations.

Having thus determined the true astronomical day at the northern station, compute by the rule for northern latitudes. For the desired local time of moonrise at the southern station change the time of moonset at the northern station twelve hours. For the desired local time of moonset at the southern station change the time of moonrise at the northern station twelve hours.

Example.—January 31, 1923, civil date, find the time of moonrise and moonset in longitude $9^{\text{h}} 40^{\text{m}}$ east from Greenwich and in latitude $37^{\circ} 50'$ south.

The longitude of the northern station is $2^{\text{h}}.3$ west from Greenwich and its latitude is $37^{\circ}.8$ N. Upon inspection of Table X it is seen that the astronomical day at the southern station is January 31 for moonrise and January 30 for moonset. the former phenomenon occurring between noon and midnight, the latter between midnight and noon. For the northern station in accordance with the precepts given above, both phenomena are to be computed for January 30.

ON THE ARRANGEMENT AND USE OF THE AMERICAN EPHEMERIS AND NAUTICAL ALMANAC.

There are in general use three different kinds of time, True Solar Time—also called Apparent Solar Time—Mean Solar Time, and Sidereal Time.

True or Apparent Solar Time is measured by the diurnal motion of the Sun, the length of the day being the interval between two successive transits of the Sun over the same meridian, and the time of day being the hour-angle of the Sun westward from the meridian. Owing to the obliquity of the ecliptic and to the lack of uniformity of the motion of the Earth in its orbit, the rate of motion of the Sun in hour-angle and the length of the apparent solar day are not constant. Therefore clocks and chronometers can not be regulated to apparent solar time, which may, however, be determined by observations of the Sun when visible.

Mean Solar Time is measured by the motion of a fictitious body called the mean Sun, which is supposed to move uniformly in the celestial equator, completing the circuit in one tropical year. Since mean solar time is uniform and regular in its passage, clocks and watches may be regulated to it, and those in ordinary use are usually so regulated.

Mean solar time can not, of course, be determined by direct observation, but may be determined indirectly by correcting observations of the Sun for the equation of time, or by converting to mean time sidereal time determined by observations of stars.

The Equation of Time is the difference in hour-angle between the true Sun and the mean Sun. The true Sun is sometimes before and sometimes behind the mean Sun by an amount which varies from zero to about 16 minutes. The equation of time is given for Greenwich mean noon on pages 2–16 and for Washington apparent noon on pages 514–521.

The Mean Solar Day is the unit of mean solar time and is equal in length to the mean or average of all the true or apparent solar days of the year. It may be otherwise defined as the interval of time elapsing between two successive transits of the mean Sun across the meridian of any place.

Sidereal Time or star time, in general terms, is measured by the diurnal motion of the fixed stars, or, speaking more precisely, by the diurnal motion of that point on the celestial equator called the vernal equinox, from which the right ascensions of the heavenly bodies are measured. Astronomical clocks regulated to sidereal time are called sidereal clocks. Sidereal time may be determined from observations of stars whose right ascensions are known.

A Sidereal Day is very nearly the length of time in which the Earth rotates on its axis and is accurately defined as the time interval between two successive transits of the vernal equinox over the same meridian. The sidereal day is shorter than the mean solar day by $3^m\ 56^s.555$ sidereal time or $3^m\ 55^s.909$ mean solar time, the tropical year of 365.2422 mean solar days containing

366.2422 sidereal days. Sidereal time and the length of the sidereal day are subject to slight irregularities on account of small differences between the positions of the true and mean equinoxes.

The mean solar and sidereal days are each divided into 24 hours. About March 23 (civil date) of each year, about two days after the vernal equinox, there is an instant when the face of a sidereal clock shows the same time as a mean time clock, and the former gains on the latter $3^m\ 56^s.555$ sidereal time per mean solar day, so that at the end of a year it will have gained one sidereal day and will again agree with the mean time clock.

The Civil Day begins at midnight and comprises 24 hours, the hours being counted from 0 to 12 in two series; the first marked A. M., running from midnight to noon, and the second, marked P. M., running from noon to midnight.

The Astronomical Day begins at noon on the civil day of the same date, the 24 hours being counted from 0 to 24, running from noon of one day to noon of the next following day. Astronomical time as well as civil time may be either apparent or mean. Astronomical time only is used throughout this volume.

The civil day begins twelve hours before the astronomical day; therefore the first half of the civil day coincides with the last half of the preceding astronomical day, and the last half of the civil day coincides with the first half of the astronomical day of the same date. Hence we have the following rules:

To convert Civil Time into Astronomical Time.—If the civil time is marked A. M., take one from the day and add twelve to the hours; if the civil time is marked P. M., take away the designation P. M. Thus, January 9, 2 o'clock, A. M., civil time, is January 8, 14^h, astronomical time; and January 9, 2 o'clock, P. M., civil time, is January 9, 2^h, astronomical time.

To convert Astronomical Time into Civil Time.—If the astronomical time is less than twelve hours, write P. M. after it; if greater than twelve hours, subtract twelve hours from it, mark the result A. M., and add one to the day.

To convert Solar or Sidereal Time of any meridian B to that of another meridian A, add the difference of longitude expressed in time when A is east of B, and subtract the difference of longitude when A is west of B.

Greenwich mean time, which at any fixed observatory is obtained by applying the longitude to the local mean time, on board ship is usually taken from the mean time chronometer set to the Greenwich time.

Greenwich mean noon of any date means the noon at the beginning of the astronomical day.

PART I.—THE EPHEMERIS FOR THE MERIDIAN OF GREENWICH.

Pages 2–17 contain for Greenwich mean noon of each day the *Sun's Apparent Right Ascension, Apparent Declination, Semidiameter, Horizontal Parallax, True Longitude, and Latitude*. They also contain the *Logarithm of the Radius Vector of the Earth, the Precession in Longitude, the Nutation in Longitude, the Aberration, the True Obliquity, the Equation of Time, the Sidereal Time or Right Ascension of Mean Sun, and the Mean Time of Sidereal Noon*. Adjoining columns contain, for each Greenwich mean noon, the *Variation per*

Hour for those of the quantities for which it seemed advisable to give a rate of motion. By multiplying any one of those variations by the hours and parts of an hour from Greenwich mean noon and adding the product algebraically to the corresponding quantity at noon, we obtain an approximate value of the quantity in question for any given Greenwich mean time. If great exactness is desired, the value of the hourly variation is found for the time halfway between Greenwich mean noon and the given Greenwich mean time before multiplying by the hours and parts of an hour from Greenwich mean noon.

It is to be noted that here, as elsewhere throughout the volume, the positive sign used with declinations or latitudes indicates north and the negative sign south.

The Sun's *Apparent Right Ascension* and *Declination* are affected both by aberration and by nutation, and therefore denote the *apparent* position of the true Sun. The Sun's *True Longitude* is the true geometric longitude not corrected for aberration; it is referred to the true equinox.

The Sun's *Latitude* is referred to the ecliptic of the date.

The Sun's *Declination* is required whenever that body is observed for the purpose of finding latitude, local time, or azimuth.

The Sun's *Semidiameter* is used in reducing the altitude of the upper or lower limb of the Sun to the altitude of the center; and in reducing the angular distance between the limb of the Sun and any other object to the distance from the center of the Sun.

The *Horizontal Parallax* is the angle subtended by the equatorial radius of the Earth, as seen from the center of the Sun.

The *Precession in Longitude* is the quantity to be applied to the longitude of the Sun referred to the mean equinox of the beginning of the Besselian fictitious year, i. e., the instant when the Sun's mean longitude is 280° , in order to refer it to the mean equinox of date.

The *Nutation in Longitude* is the quantity to be applied to the longitude of a body referred to the mean equinox of date in order to refer it to the true equinox, short-period terms being neglected.

The *Aberration* is the quantity to be subtracted from the true longitude of the Sun in order to obtain its apparent longitude.

The *True Obliquity* is the inclination of the Earth's equator to the ecliptic, short-period terms being neglected.

The corrections to the values of the nutation and the obliquity here given, to take account of the short-period terms, may be found on pages 215-216.

The *Equation of Time* is the apparent time of Greenwich mean noon, or the hour angle of the true Sun at that instant. When interpolated to any given Greenwich mean time, it is the correction to be applied to mean time in order to obtain apparent time.

The *Sidereal Time of Mean Noon* is the right ascension of the mean Sun at Greenwich mean noon. It may be reduced for the longitude or to any Greenwich mean time by using the hourly variation, $+9^s.8565$; or by Table III, page 693 of this volume, for reducing intervals of mean time to sidereal time. It is useful in converting mean time to sidereal time. We first find the Greenwich mean time, then the right ascension of the mean Sun for that time,

and this being added to the local astronomical mean time, i. e., the hour angle of the mean Sun, will give the hour angle of the vernal equinox, or the sidereal time required.

The sidereal time of mean noon, reduced for the longitude of the place, is also used in converting sidereal time to mean time. Subtracting the reduced value from the given sidereal time gives the interval of sidereal time past noon, and that is converted into the required mean time by subtracting from it the corresponding reduction of a sidereal interval to a mean-time interval, taken from Table II, page 690 of this volume. If the sidereal interval is less than $3^m 56^s.555$, there are two mean times corresponding to the given sidereal time, one a few minutes after the preceding noon, and the other a few minutes before the following noon, the mean-time interval between these two mean times being $23^h 56^m 4^s.09$. The mean time, approximately known, will always show which one is to be taken. Instead of using Table II the reduction of a sidereal to a mean-time interval may be found by multiplying $-9^s.8296$ by the hours and parts of an hour of the sidereal interval.

The *Mean Time of Sidereal Noon* is the number of hours, minutes, and seconds after Greenwich mean noon when the vernal equinox passes the meridian of Greenwich; it may be reduced to any other meridian by using the hourly variation, $-9^s.8296$, to effect the necessary interpolation, or the reduction may be taken directly from Table II. In the same way the reduction may be made to any Greenwich sidereal time, and the result will then represent 24^h —Right Ascension of the Mean Sun. This column may be conveniently used for converting sidereal to mean time, or—which is the same problem—for finding the time of meridian passage of a star whose right ascension is known, by adding to the mean time of the *preceding* local sidereal noon, the mean time equivalent of the given sidereal time.

As examples of the use of pages 2–17:

1. Let the Sun's declination be required for April 14, 1923, $2^h 5^m 20^s$, P. M., at a place whose longitude is $58^\circ 20'$, or $3^h 53^m 20^s$ west from Greenwich:

Local mean time	April 14,	$2^h 5^m 20^s$
Longitude from Greenwich (additive)		$3^h 53^m 20^s$
Greenwich mean time	April 14,	$5^h 58^m 40^s$

Reducing the minutes and seconds to decimals of an hour, we find that this moment is $5^h.978$ after Greenwich mean noon on April 14, or $18^h.022$ before Greenwich mean noon on April 15.

On page 6 of the Ephemeris we find that the variation of declination per hour is:

At Greenwich mean noon, April 14	$+54.30''$
At Greenwich mean noon, April 15	$+53.91''$
Difference for one day	$-0.39''$

If great exactness is desired, we find the amount of this hourly variation for the time halfway between Greenwich noon and the time of observation; that is, for 3 hours after Greenwich noon of the 14th, this being half of 6 hours. Three hours is 0.125 of a day; so the calculation is as follows:

Variation at Greenwich mean noon, April 14	"	+54.30
Change in 0.125 of a day	-0".39×0.125	- 0.05
Variation at 3 hours after noon		+54.25
Declination at Greenwich noon, April 14	+9 8 9.4	
Change in 5.978 hours	+54".25×5.978	+ 5 24.3
Sun's declination at time of observation		+9 13 33.7

With equal facility the computation might have been made backward from the succeeding noon. Thus in the example just given the time is 18^h.022 before Greenwich noon of April 15; half this interval is about 0.375 of a day, and the hourly motion for the middle of the interval is +54".06. Then we find:

Declination at Greenwich noon, April 15	"	+9 29 47.9
Change in -18.022 hours	+54".06×-18.022	- 16 14.3
Sun's declination at time of observation		+9 13 33.6

It will always be well to make the calculation in both ways, as a check; but if the results differ slightly the one derived from the nearest noon should be regarded as the more accurate.

2. Let the Sun's right ascension and the equation of time be required for July 13, 1923, 10^h 3^m 30^s, A. M., mean time, at a place whose longitude is 85° 15', or 5^h 41^m west from Greenwich.

Local astronomical mean time	July 12,	^h 22 ^m 3 ^s 30
Longitude from Greenwich (additive)		5 41 0
Greenwich mean time	July 13,	^h 3 44 30=3.7417
<i>Sun's Right Ascension.</i>		<i>Equation of Time.</i>
Greenwich noon, July 13	^h 7 ^m 26 ^s 48.46	^m -5 ^s 26.10
Change in 3.7417 hours	10 ^s .172×3.7417 +38.06 -0 ^s .315×3.7417	- 1.18
	<u>7 27 26.52</u>	<u>-5 27.28</u>

In this case the hourly variations interpolated to half the interval, or 1^h.87 after noon, have been used.

3. If the sidereal time is required for the same time and place, we have:

Sidereal time at Greenwich mean noon, July 13	^h 7 ^m 21 ^s 22.36
Reduction for 3 ^h 41 ^m 30 ^s from Table III, or 9 ^s .8565×3.7417	+36.88
Add the local astronomical mean time	22 3 30.00
The required sidereal time (rejecting 24 ^h)	<u>5 25 29.24</u>

4. On July 13, 1923, A. M., at a place whose longitude is 85° 15' W., suppose the sidereal time to be 5^h 25^m 29^s.24 and that the corresponding mean time is required.

The astronomical day is July 12; the longitude in time, $+5^h 41^m 0^s$, or $+5^h.6833$.

First solution.

Sidereal time at Greenwich mean noon	July 12,	^h 7 ^m 17 ^s 25.80
Reduction for $5^h 41^m 0^s$ from Table III, or $9^s.8565 \times 5.6833$		+56.02
The sidereal time at local mean noon, July 12		7 18 21.82
The given sidereal time ($+24^h$, if necessary for the following subtraction)		29 25 29.24
Subtracting the first from the second gives the sidereal interval from noon		22 7 7.42 = $22^h.1187$
Reduction for $22^h 7^m 7^s.42$ from Table II, or $-9^s.8296 \times 22.1187$		-3 37.42
The required astronomical mean time	July 12,	22 3 30.00

Second solution.

Mean time at Greenwich sidereal noon	July 12,	^h 16 ^m 39 ^s 49.95
Reduction for longitude from Table II, or $-9^s.8296 \times 5.6833$		-55.86
Mean time of <i>preceding</i> local sidereal noon	July 12,	16 38 54.09
Add the given sidereal time		5 25 29.24
Reduction for $5^h 25^m 29^s.24$ from Table II, or $-9^s.8296 \times 5.4248$		-53.32
The required astronomical mean time	July 12,	22 3 30.01

If there is any doubt about the mean time of the *preceding* local sidereal noon, the first solution is to be preferred.

Pages 18-25 contain the rectangular coordinates of the Sun, referred to the center of the Earth as the origin, and to the true equator and equinox as the plane and point of reference. Each coordinate is given for every Greenwich mean noon and midnight. The columns *Reduc. to Mean Eq'x of 1923.0* give the corrections to be applied to the coordinates for noon in order to obtain the corresponding coordinates referred to the mean equator and equinox of the beginning of the Besselian fictitious year.

Pages 26-117 contain *The Moon's Right Ascension and Declination* for each day and hour of Greenwich mean time, referred to the true equator and equinox. They are accompanied by columns of *Variations per Minute*, by means of which interpolation may be conveniently made to any moment of Greenwich mean time. The right ascension or declination is taken out for the given day and hour of Greenwich mean time; the *Var. per Min.* is multiplied by the minutes and parts of a minute of the Greenwich time, and the product is added numerically in case of the right ascension and algebraically in case of the declination.

Thus, suppose the Moon's right ascension and declination are required for January 25, 1923, $10^h 10^m 30^s$, astronomical mean time at Greenwich:

	<i>Right Ascension.</i>	<i>Declination.</i>
	^h ^m ^s	[°] ['] ["]
January 25, 10^h	2 47 46.60	+11 56 0.8
Change in 10.5 minutes	$1^s.9876 \times 10.5$ 20.87 + $7''.292 \times 10.5$	+1 16.6
January 25, $10^h 10^m 30^s$	2 48 7.47	+11 57 17.4

For the sake of precision the differences here employed have been interpolated for $5^m.2 = 0^h.09$.

Page 117 contains also the *Phases of the Moon* and the dates of the *Moon's Apogee and Perigee*, or the greatest and least distances from the Earth.

Pages 118–133 contain for every Greenwich mean noon and midnight the *Moon's Longitude* and *Latitude* referred to the true equinox and the ecliptic, its *Semidiameter*, and its *Equatorial Horizontal Parallax*. The column adjoining that of the horizontal parallax gives the variation of that quantity per hour, by means of which it can be reduced to any other Greenwich mean time in the manner shown in the preceding examples. When allowing for change in the variation itself, note must be taken of the fact that the tabular interval is here 12 hours instead of 24. The quantity thus obtained is the equatorial horizontal parallax; to obtain the horizontal parallax at any given place, the correction for the latitude of the place must be applied. The reduction of the Moon's semidiameter may be readily found by multiplying the reduction of the horizontal parallax by 0.2725 (see page xi), or by simply computing the proportional part.

If, for example, the semidiameter of the Moon is to be taken out for March 10, 1923, 7^h, P. M., Greenwich mean time, we see that the difference of the semidiameters at noon and midnight of March 10 is 5''.9; then,

$$12^h : 7^h :: 5''.9 : 3''.4$$

which is the correction to be subtracted from the semidiameter at noon, because the semidiameter is decreasing. The Moon's semidiameter for March 10, 7^h, is therefore 15' 38''.9.

The Moon's semidiameter and horizontal parallax are required for all observations of the Moon.

Pages 118–133 contain also: The *Moon's Age*, or the time elapsed since the preceding new Moon, given to tenths of a day; the mean time of the *Moon's Transit, Upper and Lower*, at Greenwich, given to tenths of a minute; and the *Variation per Hour* of the latter quantity, that is, the variation for one hour of longitude, by means of which the local time of an upper or lower transit of the Moon may be computed for any place whose longitude is known.

Pages 134–198 contain for each of the seven major planets the geocentric ephemeris followed immediately by the heliocentric ephemeris.

The geocentric ephemeris gives the planet's *Apparent Right Ascension* and *Apparent Declination* with the respective *Variations per Hour* or *per Day*. The positions thus given are referred to the true equator and equinox, and are corrected for aberration. The geocentric ephemeris gives also the *Logarithm of Distance from Earth* with the *Variation per Hour* or *per Day*, the planet's *Semidiameter* and *Horizontal Parallax*, and, to tenths of a minute, the time of *Transit Meridian of Greenwich*. All the data, except the last named, are given for Greenwich mean noon.

The right ascension and declination of a planet are required whenever it is observed for time, latitude, or azimuth. The mode of reducing the ephemeris positions of planets to other instants of Greenwich mean time is the same as that already given for the Sun. The local mean time of meridian transit of any planet at any place can be found by dividing the proper daily difference of the ephemeris times by 24, multiplying the quotient by the longitude of the place expressed in hours and fractions, and applying the product with its proper sign to the time of Greenwich transit.

The heliocentric ephemeris gives the *Heliocentric Longitude, Mean Equinox of Date*; the *Heliocentric Latitude*; and the *Logarithm of Radius Vector*; with

their respective *Variations per Day*. The heliocentric longitude may be referred to the true equinox by applying nutation. The variations are given for the instant of Greenwich mean noon. The column *Reduction to Orbit* contains the correction to be applied to the heliocentric longitude in order to obtain the longitude measured along the orbit of the planet. This orbit longitude is equal to the distance from the mean equinox to the node, plus the distance from the node to the planet. The heliocentric latitude is referred to the ecliptic of the date. The *Logarithm of Radius Vector* is the logarithm of the distance of the center of the planet from that of the Sun.

PART II.—THE EPHEMERIS FOR THE MERIDIAN OF WASHINGTON.

Pages 200–201 contain formulæ for reducing mean positions of stars to apparent positions, including expressions for the Besselian star-numbers and star-constants, and for the independent star-numbers; the whole based upon the constants of the Paris Conference of May, 1896, and expressed in the notation of BESSEL.

Pages 202–205 contain the logarithms of the *Besselian Star-Numbers*, *A*, *B*, *C*, *D*, for each Washington mean midnight, with the values of *E* appended at the bottoms of the pages. The terms of short period have been included. These numbers serve to reduce the mean place of a star at the beginning of the Besselian fictitious year to its apparent place at any of the dates for which the numbers are given, and in ordinary cases four-figure logarithms suffice; but where extreme accuracy is desired the logarithms of *A*, *C*, and *D* are sometimes needed to five places of decimals. Along with the solar day, the first column contains the sidereal hour of Washington mean midnight for certain dates, and by interpolation among them it is easy to find the sidereal time for which any set of quantities is given.

The following is an example of the reduction of a star to apparent place by the Besselian star-numbers:

Computation of the apparent place of α Aquilæ, May 26, 1923, for the upper transit at Washington.

log <i>a</i>	0.5165	log <i>b</i>	7.2481 <i>n</i>	log <i>c</i>	8.0477	log <i>d</i>	8.8234 <i>n</i>

				$\tau\mu$	+0.001		
Apparent Place, May 26,				α	^h 18 ^m 38 ^s 5.644	δ	[°] -9 ['] 7 ^{''} 30.36

Pages 206–213 contain the *Independent Star-Numbers*, which can frequently be advantageously used instead of the *Besselian Star-Numbers*. The terms of short period have been included. These quantities are connected with those of Bessel by the relations given on page 200, which also contains the formulæ

and precepts for the application of both systems of numbers. In order to use the Besselian numbers, it is necessary to have the values of the star-constants $a, b, c, d, a', b', c', d'$, while the independent star-numbers render it possible to determine the apparent place of a star without computing these star-constants. Four-figure logarithms usually suffice, but where extreme accuracy is desired the logarithms of g and h are needed to five places of decimals, and G and H are needed to one-tenth of a minute of arc. The column τ gives the fraction of a year, counted from the beginning of the Besselian fictitious year to each date.

The following is an example of the reduction of a star to apparent place by the independent star-numbers:

Computation of the apparent place of α Aquilæ, May 26, 1923, for the upper transit at Washington

$G =$	$3^{\text{h}} 49.7^{\text{m}}$		$\delta_0 =$	$-9^{\circ} 7.6'$
$a_0 =$	$18^{\text{h}} 38.1^{\text{m}}$		$G + a_0 =$	$22^{\text{h}} 27^{\text{m}}.8$

Page 214 contains for every tenth sidereal day the *Besselian* and *Independent Star-Numbers*, exclusive of all short-period terms. They are useful in computing ephemerides of stars, similar to those on pages 316-513, for which data containing short-period terms should not be employed.

Pages 215-216 contain for Washington mean midnight of each day the short-period terms of the nutation in longitude and obliquity, for use in connection with the formulæ on page 201, and the coefficients mentioned later, which are given for each star on pages 316-513.

Pages 217-230 contain the *Mean Places of Ten-day Stars* for the beginning of the Besselian fictitious year. These pages give also the magnitude, spectral type, annual variations, and proper motions for each star. The annual variations are to be considered as the differential coefficients of each coordinate with respect to the time at the beginning of the year.

Page 231 contains, for the *Circumpolar Stars*, the same data as the immediately preceding pages do for the ten-day stars.

Pages 232-315 contain for every upper transit at Washington the apparent positions of seventeen northern and eighteen southern circumpolar stars arranged in the order of their right ascensions. The mean solar time of transit is given in the column *Washington Mean Time*, in order that each transit above

and below the pole may be readily identified. Suppose, for example, that the transit of Polaris below the pole on January 26 is to be found, and we wish to know whether it precedes or follows the upper transit of the same date. On page 232 we find that the upper transit occurs January 26.2; the lower transit, therefore, occurs January 26.7. But the lower transit of July 1 precedes the upper one, which occurs July 1.8. A transit occurring very nearly at noon may also be identified without a computation to ascertain the actual mean date, by simply noting the tenth of a day in the column *Washington Mean Time*.

The secant and tangent of the apparent declination for the 15th of each month and the mean place in right ascension and declination for the beginning of the year are given for each star at the foot of the page.

Pages 316-513 contain, for every tenth upper transit at Washington, the apparent places of 790 stars, being all those given in the list of mean places of ten-day stars. The *Washington Mean Time* in the left-hand column of each page gives the day and tenth of the transit, so that intermediate transits may be readily identified; and to facilitate interpolation, the differences of each coordinate are given for every ten days.

In connection with the ephemeris of each ten-day star there are given at the foot of the page (1) the seconds of the mean place in both right ascension and declination for the beginning of the year, (2) the secant and the tangent of the mean of the star's greatest and least apparent declinations during the year, and (3) the coefficients of the short-period terms of the nutation, the use of which is explained on page 201.

Pages 514-521 contain, for Washington apparent noon, the *Apparent Right Ascension* and *Declination* of the Sun, the *Equation of Time*, and the *Variation per Hour* of these quantities; the *Semidiameter* of the Sun, and the *Sidereal Time of Semidiameter Passing Meridian*. The last column on each page contains the *Sidereal Time of Mean Noon*.

The *Equation of Time, Mean-App.*, is the correction to be applied to apparent time in order to obtain mean time. Each number as given is the mean time of transit of the Sun's center over the meridian of Washington counted from the nearest noon.

Pages 522-537 contain the *Right Ascension of Center*, the *Geocentric Declination of Center*, the *Sidereal Time of Semidiameter Passing Meridian*, the *Geocentric Semidiameter*, and the *Equatorial Horizontal Parallax* of the Moon, and the *Washington Mean Time* at the moment of each upper and lower transit over the meridian of Washington.

The *Variation per Hour of Longitude* is the correction to be applied in each case to the quantity in the preceding column to obtain its value for the time of transit over the meridian one hour west of Washington, supposing the rate of change to be uniform and equal to what it is at the instant of transit over the meridian of Washington. The quantities in the third column, when corrected for another longitude by the hourly variations, give the local mean time of transit for that longitude. By means of the variations per hour of longitude any one of the quantities under consideration can be computed with great exactness for the moment of transit over any meridian not more than one hour

distant from Washington. To obtain the same accuracy for more distant meridians, we may proceed as follows: Let F represent either the *Washington Mean Time*, the *Right Ascension of Center*, or the *Geocentric Declination of Center*, and let V represent the corresponding *Variation per Hour of Longitude*. Write down three successive values of F , together with the corresponding values of V , and difference the latter as in the following scheme, where the middle values, F_o and V_o , belong to the culmination from which is to be derived the value of F for the culmination on the meridian whose longitude is λ :—

Function.	Var. per Hour of Longitude.	Δ'	Δ''
F_{-1}	V_{-1}		
F_o	V_o	a'	b
F_{+1}	V_{+1}	a''	

Then, for the culmination at the meridian λ

$$F\lambda = F_o + \lambda V_o + \frac{\lambda^2}{48} (a' + a'') + \frac{\lambda^3 b}{864}$$

where λ must be expressed in hours and decimals of an hour, and reckoned from Washington or from 180° from Washington according as the upper or lower culmination is used for the middle value (F_o). Adding twelve hours to the Washington time of lower transit at Washington gives the local time of upper transit at places whose longitude is 180° from Washington.

The column *Bright Limbs* is given to indicate to the observer which limbs are illuminated. When one limb is full and the terminator is within $1''$ of the opposite limb, both can be well observed, and in such cases both are indicated, the defective limb being indicated by an italic letter or numeral, and the correction for defective illumination (as seen from Washington) being given in a footnote.

Pages 538–553 contain for six of the major planets, the geocentric *Apparent Right Ascension* and *Declination*, the *Horizontal Parallax*, *Semidiameter*, *Sidereal Time of Semidiameter Passing Meridian*, and the *Washington Mean Time*, for the moments of all transits which it is usually desirable to observe over the meridian of Washington. The stellar magnitude at opposition for Jupiter, Saturn, Uranus, and Neptune, respectively, is given at the bottom of the page containing the ephemeris of the planet.

PART III.—PHENOMENA.

This part gives the dates of the principal astronomical phenomena of the year, expressed in Greenwich mean time, except in the case of the occultations visible at Washington, where Washington time is used.

Pages 556–563 contain all necessary data respecting the solar and lunar eclipses which occur during the year.

The eclipse elements are given for the moment of conjunction of the Sun and Moon in right ascension, but the subsequent tables and results are computed from the exact positions of these bodies at the several instants referred to. The times and angles designated as the circumstances of a lunar eclipse

remain the same throughout all parts of the Earth, and require no explanation beyond a mere statement of the fact that in computing them the geometrical diameter of the Earth's shadow has been augmented in the proportion of 51:50. The principal circumstances of each total and annular eclipse of the Sun are stated in five lines, as follows:—

The line entitled "Eclipse begins" gives the Greenwich mean time at which the Moon's penumbra first touches the Earth, together with the latitude and longitude of the point of contact.

The line entitled "Central eclipse begins" gives the time when the axis of the Moon's shadow first touches the Earth, together with the latitude and longitude of the point of contact.

The line entitled "Central eclipse at local apparent noon" gives the time when the axes of the Earth and of the shadow cone lie in the same plane, together with the latitude and longitude of the point where the axis of the shadow cone then cuts the Earth's surface.

The lines entitled "Central eclipse ends" and "Eclipse ends" give, respectively, the times when and the localities where these events occur, the phenomena being the converse of those denoted by the similar phrases for the beginning.

In the case of partial solar eclipses the axis of the Moon's shadow does not come into contact with the Earth, and the three lines entitled, respectively, "Central eclipse begins," "Central eclipse at local apparent noon," and "Central eclipse ends," are replaced by a single line entitled "Greatest eclipse," whereon are given the time when and the latitude and longitude where the eclipse attains its greatest magnitude. The latter phenomenon necessarily occurs with the Sun in the horizon.

Maps of the Eclipses.—The regions in which each eclipse is visible are shown upon the map relating to it, from which may be taken approximately, for any place, both the times of the beginning and ending of the eclipse and its magnitude. The dotted curves show the outline of the shadow for each hour of Greenwich mean time, and therefore pass through all places where the eclipse begins or ends at the hour indicated. To find the instant of beginning at any place, we determine by inspection between what pair of these curved lines the place is situated. The eclipse will then begin between the corresponding hours of Greenwich mean time; and the fraction of the hour may be determined by dividing the hour in the same proportion as the space representing it on the map is divided by the place in question. This division may be made a little more exact by allowing for changes in the spaces as indicated by their varying width. The Greenwich mean time thus found must be reduced to local mean time by applying the longitude.

As an example, suppose we wish to find the times at which the eclipse of Sept. 10, 1923, begins and ends at San Diego, Calif., whose latitude is $+32^{\circ} 43'$ and whose longitude is $+117^{\circ} 10'$.

For the beginning we compare the distance of the place from the curves of 7^h and 8^h and find it to correspond to about 30 minutes from the former, thus giving for the approximate time of beginning 7^h 30^m; for the end we compare the distance of the place from the curves of 10^h and 11^h and find it to

correspond to about 20 minutes from the former, thus giving for the approximate time of ending $10^h 20^m$; and both of these results are probably correct to within 3 or 4 minutes.

Changing to local mean time, we shall have—

	Beginning.			Ending.		
	d	h	m	d	h	m
Greenwich mean time	Sept. 10	7	30	10	10	20
Longitude west			7 49			7 49
Local mean time	Sept. 9	23	41	10	2	31

In the case of total and annular eclipses, a fair estimate of the magnitude of the eclipse at any place may be obtained from the position thereof relative to the central line and to the limit. On the central line the eclipse is annular or total, while between the central line and the limit the maximum magnitude of the eclipse is given by the quotient of the distance of the place from the limit divided by the distance of the central line from the limit, the measurements being made upon a line drawn through the place perpendicularly to the central line.

More Accurate Computations.—A more accurate determination of the phases, as visible at any point of the Earth's surface, may be obtained from the Besselian elements, which are given for every 10 minutes of Greenwich mean time. Their geometric signification is as follows:

Let us imagine a plane passing through the center of the Earth, perpendicular to the right line joining the centers of the Sun and Moon. This latter line is the axis of the Moon's shadow, and the plane is called the *fundamental plane* or plane of xy . We take the intersection of this plane with that of the Earth's equator as the axis of x , and the center of the Earth as the origin of coordinates. The axis of y is perpendicular to that of x , and directed toward the north; x and y are then the coordinates of the point in which the axis of the shadow intersects the fundamental plane, and they are here expressed in terms of the Earth's equatorial radius as unity. The angle d , of which the sine and cosine are both given, is the declination of that point of the celestial sphere toward which the axis of the shadow is directed; or, in other words, it is the declination of the center of the Sun as seen from the center of the Moon. The angle μ is the Greenwich hour-angle of this same point of the celestial sphere.

The quantities l_1 and l_2 are the radii of the shadow cones upon the fundamental plane, l_1 corresponding to the penumbra, and l_2 to the umbra. The notation is that of CHAUVENET'S *Spherical and Practical Astronomy*, in which l_2 is regarded as positive for an annular and negative for a total eclipse.

The angles f_1 and f_2 , the tangents of which are given, are the angles which the elements of the respective shadow cones make with the axis of the shadow; or, they are the semiangles of the two cones.

In order to facilitate interpolation to any required moment, the logarithms of x' , y' , and μ' , which are the changes of x , y , and μ , in one minute of time, are given at the bottom of the table.

The method of computing an eclipse from its Besselian elements is based on the fact that the distance of the observer from the axis of the shadow cones is equal to the radius of the penumbra at the point of observation for the beginning and ending of the eclipse, and is equal to the radius of the umbra at the

point of observation for the beginning and ending of totality or of the annular phase. To find this distance and radius in each case, we proceed as follows:

(1) The coordinates of the observer, ξ , η , and ζ , together with their variations in one minute, are computed for some assumed moment of Greenwich mean time, as near as practicable to the true time of the required phase.

(2) The coordinates x and y of the axis of the shadow, together with their variations in one minute, are taken for the same moment from the tables of elements.

(3) From (1) and (2) the position and motion of the observer relative to the axis of the shadow are found.

(4) The radius of the penumbra or umbra at a distance from the fundamental plane equal to that of the observer is also computed.

(5) Then, assuming the motions to be uniform, we determine the time required for the observer to be brought to a distance from the axis of the shadow equal to this radius.

The formulæ and directions for the several steps in the computation are as follows:—

(1) Find $\rho \cos \varphi'$ and $\rho \sin \varphi'$, which are the geocentric coordinates of the station referred to the Earth's equator, ρ being the distance from the center of the Earth and φ' the geocentric latitude. These coordinates may be computed from the following table based on the compression of the Earth adopted at the Paris Conference of 1911, 1/297, by the formulæ—

$$\rho \cos \varphi' = F \cos \varphi$$

$$\rho \sin \varphi' = \frac{\sin \varphi}{G}$$

φ being, as usual, the geographic latitude.

Table for Computing the Geocentric Coordinates of a Place.

φ	Log F .	Log G .
0°	0.00000	0.00293
5	0.00001 1	0.00292 1
10	0.00004 3	0.00289 3
15	0.00010 6	0.00283 6
20	0.00017 7	0.00276 7
25	0.00026 9	0.00267 9
30	0.00037 11	0.00256 11
35	0.00048 11	0.00245 11
40	0.00060 12	0.00232 12
45	0.00073 13	0.00220 12
50	0.00086 13	0.00207 13
55	0.00098 12	0.00195 12
60	0.00110 12	0.00183 12
65	0.00120 10	0.00173 10
70	0.00129 9	0.00164 9
75	0.00137 8	0.00156 8
80	0.00142 5	0.00151 5
85	0.00145 3	0.00148 3
90	0.00148 1	0.00146 2

For the assumed Greenwich mean time of computation, take from the table of elements the values of $\sin d$, $\cos d$, and μ . Then, with λ for the longitude west from Greenwich, the coordinates of the observer will be -

$$\begin{aligned}\xi &= \rho \cos \varphi' \sin (\mu - \lambda) \\ \eta &= \rho \sin \varphi' \cos d - \rho \cos \varphi' \sin d \cos (\mu - \lambda) = \eta_1 - \eta_2 \\ \zeta &= \rho \sin \varphi' \sin d + \rho \cos \varphi' \cos d \cos (\mu - \lambda) = \zeta_1 + \zeta_2\end{aligned}$$

and their variations in one minute of mean time will be—

$$\begin{aligned}\xi' &= [7.63986] \rho \cos \varphi' \cos (\mu - \lambda) \\ \eta' &= [7.63986] \rho \cos \varphi' \sin d \sin (\mu - \lambda) = [7.63986] \xi \sin d \\ \zeta' &\text{ is not needed.}\end{aligned}$$

(2) For the same assumed moment of Greenwich mean time, take from the table of elements the coordinates x and y of the axis of the shadow, together with their variations for one minute, which are equal to one-tenth of the differences of two consecutive numbers. These variations are represented by x' and y' , and their logarithms are given beneath the tables of x and y .

(3) The distance m and position-angle M of the axis of the shadow relative to the observer, and the relative motions, n and N , are computed by the formulæ—

$$\begin{aligned}m \sin M &= x - \xi \\ m \cos M &= y - \eta \\ n \sin N &= x' - \xi' \\ n \cos N &= y' - \eta'\end{aligned}$$

(4) Both for the umbra and for the penumbra, the radius L at the distance ζ from the fundamental plane is computed by the formula—

$$L = l - \zeta \tan f$$

l and f being taken from the table of elements, and ζ computed in (1).

(5) If the time chosen for computation is exactly that of the beginning or ending of the eclipse, we shall have—

$$m = L$$

But, as this condition will rarely be fulfilled on a first trial, a correction τ to the assumed time is computed thus: Find the angle ψ from the equation—

$$\sin \psi = \frac{m \sin (M - N)}{L}$$

There will be two values for this angle; the one for which $\cos \psi$ is negative must be taken for the beginning of the eclipse, for the beginning of the annular phase, or for the ending of the total phase, but the one for which $\cos \psi$ is positive must be taken for the ending of the eclipse, for the ending of the annular phase, or for the beginning of the total phase. The correction τ to the assumed time will then be found, in minutes, from—

$$\tau = - \frac{m \cos (M - N)}{n} + \frac{L \cos \psi}{n}$$

However, only in case the value of τ does not exceed a few minutes can the time thus corrected be considered even fairly accurate. Therefore it is best to commence the computation by assuming times near the phenomena wanted. The times for the beginning and the ending of an eclipse may be

derived from the chart with sufficient exactness as previously explained; the time for the total or for the annular phase may then be assumed as midway between the times assumed for the beginning and the ending of the eclipse; or, in case of a partial eclipse, this time midway may be assumed as that of the maximum eclipse.

The more accurate times resulting from the computation as outlined above and as illustrated in the example below may now be taken in place of those originally assumed, and the whole computation may be repeated, thus leading to a value of τ in each case, which should be very small, and which should give a very accurate time of the phenomenon. Such a repetition of the computation will be advisable, moreover, for the reason that it will enable one to locate and eliminate any accidental numerical errors that may have occurred in the first computation.

As a result of this last approximation the computed times of contact will be theoretically exact within less than a second, but the uncertainties of the solar and lunar tables are such that an unavoidable error of several seconds may exist in the prediction.

Position-angle of Point of Contact.—The position-angle P , of the point of contact, reckoned from the north point of the Sun's limb toward the east, is found by the formula—

$$P = N + \psi$$

where the results of the last approximation are used.

The position-angle V , of the point of contact, reckoned from the vertex of the Sun's limb toward the east, is found by the formula—

$$V = P - C$$

where C is obtained from

$$\tan C = \frac{\xi}{\eta}$$

$\sin C$ having the same algebraic sign as ξ , and the results of the last approximation again being used.

Time of Maximum Eclipse.—For a partial eclipse, or for a central eclipse at a point at which the eclipse is only partial indicated by $\sin \psi$ greater than unity for the umbra, the correction to the assumed time to obtain the time of maximum eclipse is given by the formula—

$$\tau = -\frac{m \cos (M - N)}{n}$$

For a central eclipse at a point at which the eclipse is total or annular, the above formula gives the correction to the assumed time to obtain the true time of mid-eclipse.

Magnitude of Maximum Partial Eclipse.—This is given by the formula—

$$D^* = \frac{L - \Delta}{2L - 0.5459}$$

where $\Delta = \pm m \sin (M - N)$, always taken positive, and L is the radius of the penumbra. In a partial eclipse D is the fraction of the Sun's diameter covered

* The denominator of this expression, as given by CHAUVENET, is $2(L - k)$; the denominator here used is obtained from CHAUVENET's by substituting 0.272274 for k , and then diminishing the result by the 1/400 part in order to allow for the fact that in deriving his formula CHAUVENET assumes the angle of the umbral cone equal to that of the penumbral.

by the Moon; but in all cases D is the ratio to the Sun's diameter of the straight line passing through the centers of the two disks and having for its extremities the Sun's limb that is nearest to the Moon's center and the Moon's limb that is nearest to the Sun's center.

Magnitude during Annular Phase.— A , the ratio of the Moon's apparent diameter to the Sun's apparent diameter, or the fraction of the Sun's diameter covered by the Moon, is given by the formula—

$$A = \frac{0.5459}{2L - 0.5459}$$

At mid-eclipse the portion of the Sun's diameter uncovered at the broadest part of the annulus is equal to $1-D$, and at the narrowest part, to $D-A$. D is computed by the formula already given.

Magnitude during Total Phase.—As in the preceding case, A , the ratio of the Moon's apparent diameter to the Sun's apparent diameter (in this case greater than unity) is given by the formula—

$$A = \frac{0.5459}{2L - 0.5459}$$

At mid-eclipse, however, the least distance between the limb of the Sun and the limb of the Moon, the Sun's diameter being taken as unity, is equal to $D-1$, and the greatest, to $A-D$.

Computation of the Solar Eclipse of September 10, 1923, for San Diego, Calif.

The position of San Diego is —

Latitude, $\phi = + 32^{\circ} 43' 0''$
Longitude, $\lambda = + 117^{\circ} 10' 0''$

and its geocentric coordinates are—

$$\begin{aligned} \rho \sin \phi' &= [9.73028] \\ \rho \cos \phi' &= [9.92541] \end{aligned}$$

From the eclipse chart we find the approximate times of the phases to be—

Pages 564–567 contain the adopted mean places and annual proper motions of such stars, as bright as magnitude 6.5, as will be occulted during the year by the Moon.

Pages 568–607 contain the elements for the prediction of the times of occultations of stars and planets by the Moon during the current year. The system of coordinates employed is similar to that already described for eclipses, the fundamental plane passing through the center of the Earth, and being taken perpendicular to the line joining the star and the center of the Moon, but the cone circumscribing the Moon and star is regarded as a cylinder which intercepts the fundamental plane in a circle having the same linear diameter as the Moon.

In the columns referring to the star, those headed *Red'ns from 1923.0* give the quantities necessary to reduce the mean place of the star at the beginning of 1923 to its apparent place at the time of occultation. These reductions are sufficiently accurate to be definitive.

Under the general head, *At Conjunction in R. A.*, are five columns giving certain quantities for the moment of geocentric conjunction of the Moon and star in right ascension, as follows:

The *Greenwich Mean Time* is the moment, T , at which the two bodies are in geocentric conjunction in right ascension. At that moment the coordinate x of the axis of the cylinder on the fundamental plane has the value zero. The column *Hour Angle, H*, gives the common geocentric hour-angle of the Moon and star at the same moment, expressed in sidereal time and counted from the meridian of Greenwich—positive toward the west and negative toward the east. Column Y gives the coordinate y of the axis of the cylinder upon the fundamental plane at the same moment. Columns x' and y' give the variations of x and y in one hour of mean time. The linear unit in these columns is the Earth's equatorial radius. The limiting parallels, north and south, show the extreme limits of latitude within which the occultation will be visible.

By the aid of these elements, the time of immersion and emersion of a star relative to the limb of the Moon may be computed for any part of the Earth by a method nearly the same as that already explained for computing eclipses, but somewhat more simple.

Prediction of Occultations for a given Place.—When it is desired to predict the circumstances of one or more occultations at any place, the first step will be to select them from the general list given in the Ephemeris. The conditions of visibility are:—

1. The limiting parallels in the last columns must include the latitude of the place.

2. The quantity $H - \lambda$, taken without regard to sign, must be less than the semidiurnal arc of the star by at least one hour. On very rare occasions an emersion might be seen in the east, or an immersion in the west, when this difference is a few minutes less than an hour.

3. The Sun must not be much more than an hour above the horizon at the local mean time $T - \lambda$, unless the star is bright enough to be seen in the daytime.

When many occultations are to be selected, the most convenient course will be to write the value of $-\lambda$ on the bottom of a slip of paper, and in passing through the list of occultations to pause over each one for which condition (1) is fulfilled, and examine by means of the slip whether conditions (2) and (3) are also fulfilled. If either fails, the computer passes on. Sometimes it will be difficult to determine whether $H-\lambda$ or $T-\lambda$ falls within the limits; and in such cases the computer may mark the occultation for trial and leave the decision for the subsequent operations. The whole list can be gone over in less than a day, and it will probably be found that about one-tenth of the occultations are marked for trial.

The next step will be to compute the local times of immersion and emersion from the elements, and to that end let—

T —the instant of geocentric conjunction of Moon and star in right ascension, expressed in Greenwich mean time;

H —the Greenwich west hour-angle of the two bodies at that moment;

λ —the longitude west of Greenwich;

$h_0 = H - \lambda$ —the local hour-angle of the star at the instant T ;

δ —the star's declination.

The procedure for each occultation will then be as follows:—

(1) The geocentric coordinates of the place, $\rho \sin \varphi'$ and $\rho \cos \varphi'$, are to be computed by the formulæ and table given in connection with eclipses on page 758.

The next step will be to find the approximate instant of apparent conjunction of the Moon and star as seen from the place, and that may be deduced from the time of geocentric conjunction by the application of an approximate correction, which must be reckoned in mean solar hours, and will be designated by the symbol t . It will have the same sign as h_0 . This correction may be computed from the formulæ—

$$\xi_0 = \rho \cos \varphi' \sin h_0$$

$$\xi' = [9.4192] \rho \cos \varphi' \cos \frac{4}{3} h_0$$

$$t = \frac{\xi_0}{\xi' - \xi}$$

By applying t to the Greenwich mean time of geocentric conjunction, as given with the elements, we shall have the Greenwich mean time of local conjunction within a few minutes.

(2) Compute for the instant $T+t$ the following quantities, in which t_0 is the sidereal equivalent of the mean time interval t :

$$\xi = \rho \cos \varphi' \sin (h_0 + t_0)$$

$$\eta = \rho \sin \varphi' \cos \delta - \rho \cos \varphi' \sin \delta \cos (h_0 + t_0) = \eta_1 - \eta_2$$

$$\xi' = [9.4192] \rho \cos \varphi' \cos (h_0 + t_0)$$

$$\eta' = [9.4192] \rho \cos \varphi' \sin \delta \sin (h_0 + t_0) = [9.4192] \xi \sin \delta$$

$$x = x't$$

$$y = Y + y't$$

Compute also m , M , n , N , and ψ from the equations—

$$m \sin M = x - \xi$$

$$m \cos M = y - \eta$$

$$n \sin N = x' - \xi'$$

$$n \cos N = y' - \eta'$$

$$\sin \psi = [0.5646] m \sin (M - N)$$

ψ being taken between the limits $\pm 90^\circ$.

Finally compute,

$$\tau = -\frac{[1.7782]m}{n} \cos (M-N) \mp \frac{[1.2135]}{n} \cos \psi$$

$$\delta\tau = \frac{[6.7591]\tau^2}{n \cos \psi} [\eta_2 \cos (N \mp \psi) - \xi \sin (N \mp \psi)]$$

where the double signs are to be taken negative for an immersion and positive for an emersion. Both τ and $\delta\tau$ thus have two values, which are expressed in minutes of time, and in order to distinguish them let those pertaining to immersion be designated, respectively, τ' and $\delta\tau'$, while those pertaining to emersion are designated τ'' and $\delta\tau''$. We then have for the Greenwich mean times of the phases,

$$\begin{aligned} \text{Instant of immersion} &= T + t + \tau' + \delta\tau' \\ \text{Instant of emersion} &= T + t + \tau'' + \delta\tau'' \end{aligned}$$

These expressions are practically exact, as the corrections $\delta\tau$ seldom amount to so much as 1.5 minutes, and whenever an inaccuracy of that magnitude is permissible they may be omitted. As a check upon the results it will be advisable to compute ξ , η , x , and y for the times of immersion and emersion finally obtained. If these times are correct, the quantities in question will fulfill the condition,

$$\sqrt{(x-\xi)^2 + (y-\eta)^2} = 0.2725$$

If $\log m \sin (M-N) > 9.4354$, $\sin \psi$ will be numerically greater than unity, and no occultation is to be expected at the given place; but a very brief one may occur if the excess of the computed distance over the Moon's semi-diameter happens to be within the errors of the ephemerides of the Moon and star.

The position-angle of the line from the Moon's center to the star, at the time of contact, is reckoned from the north point toward the east, and designated by the symbol P . It is computed from the formulæ—

$$\begin{aligned} P &= N - \psi + \delta P && \text{for immersion,} \\ \text{or } P &= N + \psi + \delta P \pm 180^\circ && \text{for emersion,} \end{aligned}$$

where the angles $N - \psi$ and $N + \psi$ are taken directly from the computation of $\delta\tau$, and δP is found in degrees of arc from the expression,

$$\delta P = \mp \frac{[7.3038]\tau^2}{\cos \psi} [\eta_2 \sin N + \xi \cos N]$$

In the latter formula the double sign is to be taken negative for an immersion and positive for an emersion.

The angle from the vertex, V , is also reckoned in the direction from the north toward the east, and is found from the formula

$$V = P - C$$

where C is computed from the expression,

$$\tan C = \frac{\xi + [8.2218]\tau\xi' - [4.9810]\tau^2\xi}{\eta + [8.2218]\tau\eta' + [4.9810]\tau^2\eta_2}$$

C being taken less or greater than 180° , according as the numerator is positive or negative.

The value of τ employed in the latter formula must be so taken as to correspond with the phase for which C is required.

As an example of an isolated occultation we will compute that of α Tauri on January 27, 1923, for Boston, Mass., whose position is—

$$\begin{aligned}\varphi &= +42^\circ 20' 58'' \\ \lambda &= + 4^h 44^m 19^s\end{aligned}$$

and whose geocentric coordinates are—

$$\begin{aligned}\rho \sin \varphi' &= [9.8262] \\ \rho \cos \varphi' &= [9.8693]\end{aligned}$$

From the elements on page 570 we have—

$$\begin{aligned}T &= 11^h 58.4^m \\ H &= + 3 51.9 \\ h_0 &= II - \lambda = - 0 52.4\end{aligned}$$

From the formulæ on page 764 we find the correction, t , to the Greenwich mean time of geocentric conjunction, T , to be about $-0^h 27^m.0$; therefore the Greenwich mean time of apparent conjunction is—

$$T+t = \text{Jan. 27, } 11^h 31^m.4$$

Pages 608-610 contain in detail all the data necessary for observing every occultation of the general list which is visible at Washington during the current year.

Page 612 contains the *Ephemeris for Physical Observations of the Sun*.

Page 613 contains certain elements referring to the Moon, its equator, and its orbit.

i = the inclination of the Moon's mean equator to the Earth's true equator.

Δ = the distance on the Moon's mean equator from its ascending node on the Earth's true equator to its ascending node on the ecliptic of date.

Ω' = the distance along the Earth's true equator from the true equinox to the ascending node of the Moon's mean equator.

Γ' = the longitude of the perigee of the Moon's orbit, referred to the mean equinox of date.

Ω = the longitude of the ascending node of the Moon's orbit on the ecliptic, referred to the mean equinox of date.

ζ = the Moon's mean longitude, referred to the mean equinox of date.

Pages 614-621 contain the *Ephemeris for Physical Observations of the Moon*.

The selenographic longitudes are measured in the plane of the Moon's equator, the axis of reference being the radius of the Moon which passes through the mean center of the visible disk positive toward the west—i. e., toward Mare Crisium—and the latitudes are measured from the Moon's equator, positive toward the north—i. e., in the hemisphere containing Mare Serenitatis.

The optical and physical librations in longitude and latitude have been computed with elements and formulæ given on page xi, and their sums are given in the second and third columns, respectively, the physical libration being given separately in the fourth and fifth columns. The Sun's selenographic colongitude (90° - longitude) and latitude and the position-angle of

the Moon's axis, C , in the sixth, seventh, and eighth columns, respectively, have all been corrected for the effect of physical libration.

When the libration in longitude is positive, the mean center of the disk is displaced toward the east—that is, the region thus exposed to view is on the west limb—and when the libration in latitude is positive the mean center of the disk is displaced toward the south—that is, the region thus exposed to view is on the north limb.

The altitude of the Sun, A , at any given time above the horizon of any point on the Moon whose selenographic longitude and latitude, λ and β , are known, may be computed from the following formula, the Sun's selenographic longitude and latitude being denoted by l_{\odot} and b_{\odot} , respectively:

$$\sin A = \sin b_{\odot} \sin \beta + \cos b_{\odot} \cos \beta \cos (l_{\odot} - \lambda)$$

Pages 622–623 contain the data with reference to the illuminated disks of Mercury and Venus. The angle θ is the angle which the arc of the great circle from the planet to the Sun makes with the arc from the planet toward the west, measured in the direction west, north, east, south. It is measured from 0° to 360° . We may also regard θ as expressing the angle which the line of cusps makes with the meridian, the positive direction of the meridian being toward the north, and the positive direction of the line of cusps that in which a person following this line would have the illuminated portion of the disk on his right.

Pages 624–625 contain the *Ephemeris for Physical Observations of Mars*. The quantities here given have been corrected for aberration, so that in using them they should be interpolated to the actual time of observation.

P —the position-angle of the axis of rotation measured eastward from the north point of the disk.

A_{\oplus} , A_{\odot} —the planetocentric right ascensions of the Earth and Sun, respectively, measured in the plane of the planet's equator from its vernal equinox.

D_{\oplus} , D_{\odot} —the planetocentric declinations of the Earth and Sun, respectively, referred to the planet's equator.

$\odot \sigma$ —the planetocentric longitude of the Sun measured in the plane of the planet's orbit from its vernal equinox.

k —the ratio of the area of the illuminated portion of the apparent disk to the area of the entire apparent disk regarded as circular.

i —the angle between the Sun and the Earth as seen from the planet.

q —the angular value of the greatest defect of illumination as seen from the Earth.

Q —the position-angle of the radius of the disk which passes through the point of greatest defect of illumination—that is, of the radius perpendicular to the line joining the cusps. It is measured eastward from the north point of the disk.

The column headed *Central Meridian* contains the longitude of the meridian which bisects the disk, measured from the adopted zero meridian.

The columns headed *Mean Time of Transit of Zero Meridian* contain the Greenwich Mean Time of every transit of the zero meridian across the actual center of the disk.

Pages 626–629 contain the *Ephemeris for Physical Observations of Jupiter*.

The columns headed *Central Meridian* contain the longitudes of the meridian which bisects the disk, measured from the adopted zero meridian of System I and System II, respectively.

The column headed *Transit of Zero Meridian* contains the Greenwich Mean Time of every fifth transit of the zero meridian across the center of the illuminated disk.

Pages 630-655 contain, concerning the *Satellites of Jupiter*, the diagram of the orbits of Satellites I-V, the times of conjunction of Satellites I-IV, the times of elongation of Satellite V, the differences in right ascension and declination between Jupiter and Satellites VI and VII, and the phenomena of Satellites I-IV together with their configurations.

a, b = the major axis and minor axis, respectively, of the outer ellipse of the outer ring.

B = the Saturnicentric latitude of the Earth referred to the plane of the rings, positive toward the north.

ω —the distance in the plane of the rings from their ascending node on the Earth's equator to their ascending node on the ecliptic.

B' —the Saturnicentric latitude of the Sun referred to the plane of the rings, positive toward the north.

$U^{\circ}+180^{\circ}$ =the Saturnicentric longitude of the Sun measured in the plane of the rings from their ascending node on the ecliptic.

Pages 657- 665 contain, concerning the *Satellites of Saturn*, the diagram of the orbits of the seven inner satellites, the times of elongation for the first eight satellites, the differences in right ascension and declination between Saturn and Phœbe, the ninth satellite, and tables for predicting the position-angles and distances from the center of the planet of the first eight satellites.

Page 666 contains the diagram of the orbits of the satellites of Uranus, together with the times of their elongations.

Pages 667–668 contain tables for predicting the position-angles and distances from the center of the planet of the satellites of Uranus and Neptune.

Page 669 contains the diagram of the orbit of the satellite of Neptune, together with the times of its elongations.

Pages 670–671 contain the *Phænomena*, or the configurations of the Sun, Moon, and planets, expressed in the symbols of page xviii. The predicted times of the conjunctions, quadratures, and oppositions of the planets with respect to the Sun are, respectively, the instants when the longitude of each planet differs from that of the Sun by 0° , $\pm 90^\circ$, or 180° . For the conjunction of the planets with the Moon and with each other, the predicted times are the instants when the two bodies have the same right ascension. In the case of conjunction the degrees and minutes to the right indicate the difference of declination. Thus, $\delta \varphi \subset \dots \varphi - 4^\circ 22'$ would be read “Conjunction of Mars with the Moon, Mars, $4^\circ 22'$ to the South.”

These pages contain also the beginning of the seasons; the perihelia and aphelia of the planets, including the Earth; the passage of the planets through the nodes of their orbits upon the ecliptic; and the date of lunar and solar eclipses, with their aspect as seen from Washington.

Pages 672-683 contain the *Positions of Observatories*, together with a list of the authorities from which the positions are obtained. The tabular arrangement is self-explanatory.

Page 684 contains two examples in the computation of lunar distances, which are inserted because lunar distance tables are no longer published.

Pages 685-744 contain a series of tables numbered from I to X.

Table I—For *Finding the Latitude by an Observed Altitude of Polaris*.

Table II—For converting *Sidereal into Mean Solar Time*.

Table III—For converting *Mean Solar into Sidereal Time*.

Table IV—For finding the *Azimuth of Polaris at All Hour Angles*.

Table V—For finding the *Azimuth of Polaris at Elongation*.

Table VI—For *Finding the Times of Upper and Lower Culmination of Polaris*.

Table VII—For finding the *Apparent Place, Time of Upper Culmination, and Time Interval between Upper Culmination and Elongation*, of Polaris.

Table VIII—For finding the time of *Sunrise and Sunset* at any place between the equator and 60° north latitude, assuming this to be the instant when the true zenith distance of the Sun's center is $90^\circ 50'$; i. e., when the apparent zenith distance of the Sun's upper limb is $90^\circ, 34'$ having been allowed for horizontal refraction and $16'$ for semidiameter.

Table IX—*Sunrise and Sunset for Southern Latitudes*.

Table X—For finding the time of *Moonrise and Moonset* at any place between 60° north latitude and 60° south latitude, assuming this to be the instant when the true geocentric zenith distance of the Moon's center is $90^\circ 50'$ minus the Moon's parallax. Here, as in the case of the Sun, $34'$ has been allowed for horizontal refraction and $16'$ for semidiameter.

GENERAL INDEX.

	Page.
Abbreviations	xviii
Aberration, Constant of	xvi
of the Sun	3
Achernar (Alpha Eridani), Apparent Place	328
Mean Place	217
Age of the Moon	118
Alcyone (Eta Tauri), Apparent Place	348
Mean Place	219
Aldebaran (Alpha Tauri), Apparent Place	354
Mean Place	219
Algol (Beta Persei), Apparent Place	343
Mean Place	218
Alioth (Epsilon Ursæ Majoris), Apparent Place	420
Mean Place	224
Alkaid (Eta Ursæ Majoris), Apparent Place	424
Mean Place	224
Alpha Canis Majoris (Sirius), Apparent Place	374
Mean Place	221
Orbit Position	x
Parallax	ix
Alpha Canis Minoris (Procyon), Apparent Place	381
Mean Place	221
Orbit Position	x
Parallax	ix
Alpha Centauri, Apparent Place	431
Mean Place	225
Orbit Position	x
Parallax	ix
Alpha Ursæ Minoris (Polaris), Apparent Place	232, 709
Mean Place	231
Polaris Tables	685
Alpheratz (Alpha Andromedæ), Apparent Place	316
Mean Place	217
Altair (Alpha Aquilæ), Apparent Place	476
Mean Place	228
Parallax	ix
Anniversaries and Festivals	xiv
Antares (Alpha Scorpii), Apparent Place	448
Mean Place	226
Aphelia of Planets	670
Apogee of Moon	117
Apparent Place of 2 Aquilæ, Example of Reduction to	752
Places of 790 Standard Stars	316
of 35 Circumpolar Stars	232
of 825 Stars, Index to	771
Arcturus (Alpha Boötis), Apparent Place	428
Mean Place	224
Ariel, First Satellite of Uranus	666, 667, 668

	Page.
Arrangement and Use of the American Ephemeris	745
Aspects of the Planets	670
Astronomical Constants	xvi
Azimuth of Polaris at all Hour Angles, Table IV	697
at Elongation, Table V	702
Beginning of the Seasons	670
Bellatrix (Gamma Orionis), Apparent Place	362
Mean Place	220
Besselian Elements of Solar Eclipses	558, 560
Formulae for Star Reductions	200
Star Numbers	202, 214
Example of Reduction with	752
Exclusive of short-period Terms	214
Betelgeux (Alpha Orionis), Apparent Place	367
Mean Place	220
Brilliancy of the Planets, greatest (see Stellar Magnitude under each planet).	
Canopus (Alpha Argus), Apparent Place	371
Mean Place	220
Capella (Alpha Aurigæ), Apparent Place	361
Mean Place	220
Castor (Alpha Geminorum), Apparent Place	380
Mean Place	221
Charts of Solar Eclipses	following pages 558, 560
Chronological Eras and Cycles	xv
Circumpolar Stars, Apparent Places	232
Mean Places	231
Conjunctions of Planets	670
Constants, Astronomical	xvi
Culminations, Moon	522
of Polaris, Table VI for finding times of	708
Upper Culmination, Meridian of Greenwich, Table VII	709
Cygni 61, Apparent Place	487
Mean Place	229
Parallax	ix
Day, Civil and Astronomical	746
Length of	xvi
of Julian Period	xv
Delta Cassiopeiæ, Apparent Place	326
Mean Place	217
Used for finding time of culmination of Polaris (Table VI)	708
Deneb (Alpha Cygni), Apparent Place	483
Mean Place	228
Denebola (Beta Leonis), Apparent Place	412
Mean Place	223
Dione, Fourth Satellite of Saturn	657, 660, 662, 664
Disk of Mercury	622
of Venus	623
Distance, Astronomical Unit of	xvi
of the Moon	xvi
of the Planets (see also reference under each planet)	xvii
of the Sun	xvi, 3
Dominical Letter	xv
Earth, Dimensions of	xvi
Elements of Orbit of	xvii
Earth's Radius Vector, Logarithm of	3
Easter, Date of	xiv

	Page.
Eccentricities of the Orbits of the Earth and Planets	xvii
Eclipses, Solar and Lunar, Elements and Circumstances of	556
Solar, Besselian Elements of	558, 560
Charts of	following pages 558, 560
Correction to Elements of	x
Example of the Computation of	761
Ecliptic, Obliquity of	3
Election Day, Date of	xiv
Elements of Planetary Orbits	xvii
Elongations of Planets	670
Elongation, Azimuth of Polaris at, Table V	702
of Polaris, Time Interval from Upper Culmination, Table VII	709
Enceladus, Second Satellite of Saturn	657, 659, 662, 664
Epact	xv
Ephemeris for the Meridian of Greenwich (Part I)	1-198
of Washington (Part II)	199-553
Equation of time for Greenwich Mean Noon	2
for Washington Apparent Noon	514
Equator, Moon's	613
Equinoxes, Date of	670
Errata	vi
Example of the Computation of Lunar Distances	684
of Occultations	766
of Solar Eclipses	761
Reduction of Stars to Apparent Place	752
of the Sun	748
Festivals, etc.	xiv
Fomalhaut (Alpha Piscis Australis), Apparent Place	503
Mean Place	230
Geocentric Ephemerides of the Planets	134
Latitude of Observatories, Reduction to	672
Golden Number	xv
Gravity, Acceleration due to	xvi
Gaussian, Constant of	xvi
Greenwich Ephemeris (Part I)	1-198
Hayford's Spheroid	xvi
Heliocentric Coordinates of the Planets	142
Hyperion, Seventh Satellite of Saturn	657, 660, 663, 665
Iapetus, Eighth Satellite of Saturn	657, 660, 663, 665
Independent Star-Numbers	206, 214
Example of Reduction with	753
Exclusive of short-period Terms	214
Formulee for	200
Irradiation	xi
Julian Period	xv
Jupiter, Diameter, Apparent Equatorial	627
Distance from Earth, logarithm of	174
Elements of Orbit of	xvii
Ephemeris for Physical Observations of	626
Elements used	xii
Greenwich, Transit of	174
Heliocentric Longitude and Latitude of	182
Horizontal Parallax of	174, 546
Radius Vector (Distance from Sun), logarithm of	182

	Page.
Jupiter, Reduction to Orbit	182
Right Ascension and Declination at Greenwich Mean Noon	174
at Washington Transit	546
Satellites, Diagram of Apparent Orbits of, Synodic Periods of	630
I, II, III, and IV, Phenomena and Configurations of	634
Times of Superior Conjunction of	631
Satellite V, Greatest Elongation of	631
Satellites VI and VII, Differential Coordinates of	633
Semidiameter, Adopted Constant of	xvii
Polar	174, 546
Sidereal Time of, Passing Meridian	546
Stellar Magnitude of	546, 626
Washington Transit of	546
Latitude, for finding, by an Observed Altitude of Polaris, Tables I, Ia	685
Formula for Reduction to Geocentric	xvi
Heliocentric, of the Planets	142
of the Moon	118
Corrections to	x
of the Sun	3
Length of the Day	xvi
of the Month	xvi
of the Seconds Pendulum	xvi
of the Year	xvi
Libration of the Moon	614
Light, Velocity of	xvi
Longitude, Heliocentric, of the Planets	142
Mean, of the Moon	613
Nutation in	3
of the Sun	3
of the Moon, Corrections to	x
Precession in	3
Short-Period Terms of Nutation in	215
True, of the Moon	118
Lunar Distances, Examples in	684
Magnitudes, Stellar, of Jupiter	546, 626
of Mars	624
of Mercury	622
of Neptune	552
of Saturn	548, 656
of Uranus	550
of Venus	623
Maps of Solar Eclipses	following pages 558, 560
Markab (Alpha Pegasi), Apparent Place	503
Mean Place	230
Mars, Distance from Earth, logarithm of	162
Elements of Orbit of	xvii
Ephemeris for Physical Observations of	624
Elements used	xii
Greenwich Transit of	162
Heliocentric Longitude and Latitude of	170
Horizontal Parallax of	162
Occultation of	570
Radius Vector (Distance from Sun), logarithm of	170
Reduction to Orbit	170
Right Ascension and Declination at Greenwich Mean Noon	162

	Page.
Mars, Semidiameter, Adopted Constant of	xvii
Apparent	162
Stellar Magnitude of	624
Mass of Planets	xvii
Mean Places of 790 Standard Stars	217
of 35 Circumpolars	231
of Stars Occulted by the Moon	564
Mean Solar into Sidereal Time, Table III	693
Mercury, Apparent Disk of	622
Distance from Earth, logarithm of	134
Elements of Orbit of	xvii
Greenwich Transit of	134
Heliocentric Longitude and Latitude of	142
Horizontal Parallax of	134, 538
Radius Vector (Distance from Sun), logarithm of	142
Reduction to Orbit	142
Right Ascension and Declination at Greenwich Mean Noon	134
at Washington Transit	538
Semidiameter, Adopted Constant of	xvii
Apparent	134, 538
Sidereal Time of, Passing Meridian	538
Stellar Magnitude of	622
Washington Transit of	538
Meridian Passage of Jupiter	174, 546
of Mars	162
of Mercury	134, 538
of Moon	118, 522
of Neptune	196, 552
of Saturn	184, 548
of Sun	514
of Uranus	193, 550
of Venus	150, 542
Mimas, First Satellite of Saturn	657, 658, 662, 664
Mira (Omicron Ceti), Apparent Place	335
Mean Place	218
Mizar (Zeta Ursæ Majoris), Apparent Place	422
Mean Place	224
Used for finding time of Culmination of Polaris (Table VI)	708
Month, Length of	xvi
Moon, Age of, Greenwich Mean Noon and Midnight	118
Apogee and Perigee	117
Bright Limbs	522
Corrections to the Long., Lat., and Hor. Parallax of the	x
Culminations, upper and lower, Meridian of Washington	522
Distance from Earth, Mean	xvi
Eclipses of, Elements and Circumstances	556
Ephemeris for Physical Observations of	614
Formula used	xi
Hourly	26
Equator, Position of	613
Libration, Formulæ for computing	xii
Longitude and Latitude of	118
Formulæ for	vii
Longitude, Mean	613
True	118

	Page.
Moon, Motion of, in Mean Longitude	613
Node, Mean Longitude of	613
Parallax for Greenwich Noon and Midnight	118
for Washington, upper and lower transit	522
Mean Equatorial Horizontal	xvi
Perigee and Apogee	117
Perigee, Mean Longitude of	613
Phases of	117
Right Ascension and Declination for each Hour	26
for Washington upper and lower Transit	522
Semidiameter, Adopted Constant of	xi, xvii
Apparent	118, 522
Sidereal Time of, Passing Meridian	522
Transit, upper and lower, at Greenwich	118
at Washington	522
Moonrise and Moonset, Table X	728
Neptune, Distance from Earth, logarithm of	196
Elements of Orbit of	xvii
Greenwich Transit of	196
Heliocentric Longitude and Latitude of	198
Horizontal Parallax of	196, 552
Radius Vector (Distance from Sun), logarithm of	198
Reduction to Orbit	198
Right Ascension and Declination at Greenwich Mean Noon	196
at Washington Transit	552
Satellite, Diagram of Apparent Orbit of	669
Sidereal Period of	669
Tables for Determining Position Angle and Distance of	668
Times of elongation of	669
Semidiameter, Adopted Constant of	xvii
Apparent	196, 552
Sidereal Time of, Passing Meridian	552
Stellar Magnitude of	552
Washington Transit of	552
Node, Mean Longitude of the Moon's	613
Nutation, Constant of	xvi
Formulae for	viii
Terms of Short Period in the	215
in Longitude	3
Oberon, Fourth Satellite of Uranus	666, 667, 668
Obliquity of the Ecliptic, True	3
Mean	xvi
Short-Period Terms of Nutation in	215
Observatories, Positions of, etc.	672
Occultations, Elements for Prediction of	568
Example of Computation of	766
Mean Places of Stars	564
Visible at Washington	608
Opposition of Planets	670
Orbits of the Planets, Elements of	xvii
Orbit Positions of Sirius, Procyon, and α^2 Centauri	x
Parallax, Annual, of τ Ceti, ϵ Eridani, Sirius, Procyon, α Centauri, Altair, and 61 Cygni	ix
Corrections to, of the Moon	x
Horizontal, of Jupiter	174, 546
of Mars	162

	Page.
Parallax, Horizontal, of Mercury	134, 588
of Moon	xvi, 118, 522
of Neptune	196, 552
of Saturn	184, 548
of Sun	2
of Uranus	193, 550
of Venus	150, 542
Solar, Constant of	vii, xvi
Pendulum, Length of Seconds	xvi
Perigee of the Moon	117
Longitude of Moon's	613
Perihelia of Planets	xvii, 670
Phases of Eclipses of Jupiter's Satellites	635
of the Moon	117
Phenomena, Eclipses, Occultations, Satellites, etc., Part III	555
of Jupiter's Satellites	634
Planetary Configurations	670
Phœbe, Ninth Satellite of Saturn	657, 661
Physical Observations of Jupiter, Ephemeris for	626
of Mars, Ephemeris for	624
of the Moon, Ephemeris for	614
of the Sun, Ephemeris for	612
Planetary Configurations	670
Orbits, Elements of	xvii
Planets, Aspects of	670
at Greatest Brilliancy (see Stellar Magnitude under each planet).	
at Stationary Points	670
in Ascending and Descending Node	670

of Stars to Apparent Place, Formulæ for	200
Example of	752
Regulus (Alpha Leonis), Apparent Place	399
Mean Place	222
Rhea, Fifth Satellite of Saturn	657, 660, 663, 665
Rigel (Beta Orionis), Apparent Place	360
Mean Place	220
Rings of Saturn	656
Roman Indiction	xv
Satellites of Jupiter	630
of Neptune	668
of Saturn	657
of Uranus	666
Saturn, Distance from Earth, logarithm of	184
Elements of Orbit of	xvii
Greenwich Transit of	184
Heliocentric Longitude and Latitude of	192
Horizontal Parallax of	184, 548
Occultations of	569, 572, 575, 578, 581, 583, 586, 589, 592, 595
Radius Vector (Distance from Sun), logarithm of	192
Reduction to Orbit	192
Right Ascension and Declination at Greenwich Mean Noon	184
at Washington Transit	548
Rings, Elements for Determining Geocentric Position of	656
Satellites, Diagram of Apparent Orbits of	657
Differential Coordinates of Phœbe	661
Greatest Elongations of	658
Names of	657
Synodic Periods of	657
Tables for Determining Position Angle and Distance	662
Semidiameter, Adopted Constant of	xvii
Apparent Polar	184, 548
Sidereal Time of, Passing Meridian	548
Stellar Magnitude of	548, 656
Washington Transit of	548
Schedir (Alpha Cassiopeïæ), Apparent Place	320
Mean Place	217
Seasons, Beginning of	670
Semidiameter of Jupiter	174, 546
of Mars	162
of Mercury	134, 538
of Moon	118, 522
of Neptune	196, 552
of Saturn	184, 548
of Sun	2, 514
of Uranus	193, 550
of Venus	150, 542
Semidiameters of the Sun and Moon, Adopted Constants of	xi, xvii
of the Planets, Adopted Constants of	xvii
Short-Period Terms of Nutation	215
in Star Numbers	200
Sidereal into Mean Solar Time, Table II	690
Noon, Greenwich Mean Time of	3
Time of Washington Mean Noon	514
Sidereal Time or Right Ascension of Mean Sun	2

	Page.
Signs of the Zodiac	xviii
Sirius (Alpha Canis Majoris), Apparent Place	374
Mean Place	221
Orbit Position	x
Parallax	ix
Solar Cycle	xv
Ephemeris	2, 514
into Sidereal Time, Table III	693
Solstices	670
Spheroid, Hayford's	xvi
Spica (Alpha Virginis), Apparent Place	422
Mean Place	224
Stars, Apparent Places of 790 Standard	316
of 35 Circumpolar	232
Elements of Occultations	568
Example of Reduction to Apparent Position	752
Formulae for Reduction to Apparent Position	ix, 200
Index to the Apparent Places	771
Mean Places for beginning of the Year, of 790 Standard	217
of 35 Circumpolar	231
of Stars Occulted by the Moon	564
Occultations visible at Washington	608
Star Numbers, Besselian and Independent, omitting short-period terms	214
Besselian, including short-period terms	202
Formulae used in Computing	viii, 200
Independent, including short-period terms	206
Sun, Aberration of	3
Constant of	xvi
Coordinates, rectangular	18
Formulae for	vii
Distance from Earth, Mean	xvi
Distance from Earth at Gr. Mean Noon, logarithm of	3
Eclipses of, Charts	following pages 558, 560
Elements and Circumstances of	556
Example of Computation of	761
Ephemeris for Physical Observations of	612
Formulae used	xi
Examples in the Reduction of	748
Longitude and Latitude, Greenwich Mean Noon	3
Mean, R. A. of, at Greenwich Mean Noon	2
Parallax, Constant of	vii, xvi
Horizontal	2
R. A. and Decl. at Greenwich Mean Noon	2
at Washington Apparent Noon	514
Semidiameter, Adopted Constant of	xi, xvii
Apparent	2, 514
Sidereal Time of, Passing Meridian	514
Sunrise and Sunset for Northern Latitudes, Table VIII	710
for Southern Latitudes, Table IX	726
Symbols and Abbreviations	xviii
Synodic Month, Length of	xvi
Periods of the Planets	xvii
Terms of Short Period in the Nutation	215
Tethys, Third Satellite of Saturn	657, 659, 662, 664
Thanksgiving Day, Date of	xiv
Time, Equation of, at Greenwich Mean Noon	2
at Washington Apparent Noon	514

	Page.
Time, Mean, of Greenwich Sidereal Noon	3
Precepts for Conversion of	746
Sidereal, of Greenwich Mean Noon	2
of Washington Mean Noon	514
Tables for Conversion of Sidereal to Solar and <i>vice versa</i> , Tables II and III	690
Titan, Sixth Satellite of Saturn	657, 660, 663, 665
Titania, Third Satellite of Uranus	666, 667, 668
Transit of the Moon	118, 522
of the Planets	134, 538
Tropical Year, Length of	xvi
Umbriel, Second Satellite of Uranus	666, 667, 668
Unit of Distance, Astronomical	xvi
Uranus, Distance from Earth, logarithm of	193
Elements of Orbit of	xvii
Greenwich Transit of	193
Heliocentric Longitude and Latitude of	195
Horizontal Parallax of	193, 550
Occultations of 582, 585, 588, 591, 594, 597, 599, 602, 605, 610	195
Radius Vector (Distance from Sun), logarithm of	195
Reduction to Orbit	195
Right Ascension and Declination at Greenwich Mean Noon	193
at Washington Transit	550
Satellites, Diagram of Apparent Orbits of	666
Greatest Elongations of	666
Sidereal Periods of	666
Tables for Determining Position Angle and Distance of	667
Semidiameter, Adopted Constant of	xvii
Apparent	193, 550
Sidereal Time of, passing Meridian	550
Stellar Magnitude of	550
Washington Transit of	550
Vega (Alpha Lyrae), Apparent Place	466
Mean Place	227
Venus, Apparent Disk of	623
Distance from Earth, logarithm of	150
Elements of Orbit of	xvii
Greenwich Transit of	150
Heliocentric Longitude and Latitude of	158
Horizontal Parallax of	150, 542
Occultations of	569, 582
Radius Vector (Distance from Sun), logarithm of	158
Reduction to Orbit	158
Right Ascension and Declination at Greenwich Mean Noon	150
at Washington Transit	542
Semidiameter, Adopted Constant of	xvii
Apparent	150, 542
Sidereal Time of, passing Meridian	542
Stellar Magnitude of	623
Washington Transit of	542
Washington Ephemeris (Part II)	199-553
Year, Length of	xvi
Zeta Ursæ Majoris (Mizar), Apparent Place	422
Mean Place	224
Used for finding time of Culmination of Polaris, Table VI	708
Zodiac, Signs of	xviii
